SELECT SUBJECTS.

Published by the fame Author.

1. A STRONOMY explained upon Sir ISAAC NEWTON's Principles, and made eafy to those who have not fludied *Mathematics*. To which is added, the Method of finding the Diffances of the Planets from the Sun, by the TRANSIT of VENUS over the Sun's Dife in the Year 1761. These Diffances deduced from that Transit; and an account of Mr. HORROX's Observations of the Transit in the Year 1639: Illustrated with 18 Copper-plates. A New Edition, Octavo.

2. An Eafy Introduction to ASTRONOMY, for young GENTLEMEN and LADIES: Definibing the Figure, Motions, and Dimenfions of the Earth; the different Seafons; Gravity and Light; the Solar Syftem; the Transit of Venus, and its U(e in Aftronomy; the Moon's Motion and Phases; the Eclipfes of the Sun and Moon: the Caufe of the Ebbing and Flowing of the Sea, &c. Second Edition, Price ς s.

3. TABLES and TRACTS relative to feveral Arts and Sciences. Price 5 s.

4. An Introduction to ELECTRICITY, in fix Sections. 1. Of Electricity in general. 2. A Defcription of the Electrical Machine. 3. A Defcription of the Apparatus (belonging to the Machine) for making Electrical Experiments. 4. How to know if the Machine be in good order for performing the Experiments, and to put it in order if it be not. 5. How to make the Electrical Experiments, and to preferve Buildings from Damage by Lightning. 6. Medical Electricity. Price ςs .

5. Select Mechanical Exercises, flewing how to confruct different Clocks, Otreries, and Sun Dials, on plain and easy Principles. With feveral Miscellaneous Articles and Tables. Illustrated with Copperplates. To which is prefixed, a flort Account of the Life of the Author. Price 5 s.

6. The Art of Drawing in Perspective made easy to those who have no previous Knowledge of the Mathematics. Illustrated with Plates. Price 5 s.

TOHIS

DEDICATION

ROYAL HIGHNESS Prince E D W A R D.

SIR, w diw noticions

A S Heaven has infpired your ROYAL HIGHNESS with fuch love of ingenious and ufeful arts, that you not only ftudy their theory, but have often condefcended to honour the professions of mechanical and experimental philosophy with your pre-A 3 fence

DEDICATION.

fence and particular favour; I am thereby encouraged to lay myfelf and the following work at your ROYAL HIGH-NESS'S feet; and at the fame time beg leave to express that veneration with which I am,

SIR,

Your ROYAL HIGHNESS'S Moft obliged, And moft obedient, Humble Servant,

JAMES FERGUSON.

THE

PREFACE.

EVER fince the days of the LORD CHAN-CELLOR BACON, natural philosophy bath been more and more cultivated in England. THAT great genius first set out with taking a general furvey of all the natural sciences, dividing them into distinct branches, which be enumerated with great exactness. He inquired scrupulously into the degree of knowledge already attained to in each, and drew up a list of what still remained to be discovered: this was the scope of his first undertaking. Afterward he carried his views A 4 much

much farther, and shewed the necessity of an experimental philosophy, a thing never before thought of. As he was a professed enemy to systems, he considered philosophy, no otherwise than as that part of knowledge which contributes to make men better and happier : he seems to limit it to the knowledge of things useful, recommending above all the study of nature, and shewing that no progress can be made therein, but by collesting fasts, and comparing experiments, of which he points out a great number proper to be made.

But notwithstanding the true path to science was thus exactly marked out, the old notions of the schools so strongly posses and a posses at that time, as not to be eradicated by any new opinions, how rationally soever advanced, until the illustrious Mr. BOYLE, the first who pursued LORD BACON'S plan, began to put experiments in practice with an affiduity equal to his great talents. Next, the ROYAL SOCIETY being established, the true philosophy began to be the reigning taste of the age, and continues so to this day.

The

3

viii

The immortal SIR ISAAC NEWTON infifted even in his early years, that it was high time to banifb vague conjectures and hypothefes from natural philofophy, and to bring that fcience under an entire fubjection to experiments and geometry. He frequently called it the experimental philofophy, fo as to exprefs fignificantly the difference between it and the numberlefs fystems which had arifen merely out of the conceits of inventive brains: the one fubfisting no longer than the spirit of novelty lasts; the other never failing whils the nature of things remain unchanged.

The method of teaching and laying the foundation of physics, by public courses of experiments, was first undertaken in this kingdom, I believe, by Dr. JOHN KEILL, and fince improved and enlarged by Mr. HAUKSBEE, Dr. DESAGULIERS, Mr: WHISTON, Mr. COTES, Mr. WHITESIDE, Dr. BRADLEY, our late Regius and Savilian professor of Astronomy, and the Reverend Dr. BLISS his fuccesfor.

Nor

X

Nor has the fame been neglected by Dr. JAMES, and Dr. DAVID GREGORY, Sir ROBERT STEWART, and after him Mr. MACLAURIN. Dr. HELSHAM in Ireland, Meffieurs s'GRAVESANDE and MUSCHENBROEK, and the Abbé NOLLET in France, have also acquired just applause thereby.

The fubstance of my own attempt in this way of instrumental instruction, the following sheets (exclusive of the astronomical part) will shew: the satisfaction they have generally given, read as lectures to different audiences, affords me some hope that they may be favourably received in the same form by the Public.

I ought to observe, that though the five last lectures connot be properly said to concern experimental philosophy, I considered, however, that they were not of so different a class, but that they might, without much impropriety, be subjoined to the preceding ones.

My

XI

My apparatus (part of which is defcribed bere, and the reft in a * former work) is rather fimple than magnificent; which is owing to a particular point I had in view. at firft fetting out, namely, to avoid all fuperfluity, and to render every thing as plain and intelligible as I thought the fubject would admit of.

* Aftronomy explained upon SIR ISAAC NEWTON'S principles, and made easy to those who have not studied mathematics.

LECT. I.

Of Matter and its Properties.

A S the defign of the first part of this course is to explain and demonstrate those laws by which the material universe is governed, regulated, and continued; and by which the various appearances in nature are accounted for; it is requisite to begin with explaining the properties of matter.

By the word *matter* is here meant every thing Matter, that has length, breadth, and thicknefs, and what. refifts the touch.

The inherent properties of matter are folidity, Its proinactivity, mobility, and divifibility.

The *folidity* of matter arifes from its having solidity. length, breadth, thicknefs; and hence it is that all bodies are comprehended under fome fhape or other, and that each particular body hinders all others from occupying the fame part of fpace which it poffeffeth. Thus, if a piece of wood or metal be fqueezed ever fo hard between two plates, they cannot be brought into contract. And even water or air has this property; for if a fmall quantity of it be fixed between any other bodies,

bodies, they cannot be brought to touch one another.

Inactivity.

A fecond property of matter is *inativity*, or *paffivenefs*; by which it always endeavours to continue in the flate that it is in, whether of reft or motion. And therefore, if one body contains twice or thrice as much matter as another body does, it will have twice or thrice as much inactivity; that is, it will require twice or thrice as much force to give it an equal degree of motion, or to flop it after it hath been put into fuch a motion.

That matter can never put itfelf into motion is allowed by all men. For they fee that a flone, lying on the plane furface of the earth, never removes itfelf from that place, nor does any one imagine it ever can. But most people are apt to believe that all matter has a propensity to fall from a state of motion into a state of reft; because they see that if a stone or a cannon-ball be put into ever so violent a motion, it foon stops; not considering that this stoppage is caused, 1. By the gravity or weight of the body, which finks it to the ground in spite of the impuls; and, 2. By the resistance of the air through which it moves, and by which its velocity is retarded every moment till it falls.

A bowl moves but a fhort way upon a bowling-green; becaufe the roughnefs and unevennefs of the graffy furface foon creates friction enough to ftop it. But if the green were perfectly level, and covered with polifhed glafs, and the bowl were perfectly hard, round, and fmooth, it would go a great way farther; as it would have nothing but the air to refift it; if then the air were taken away, the bowl would go on without any friction, and confequently without any

any diminution of the velocity it had at fetting out : and therefore, if the green were extended quite around the earth, the bowl would go on, round and round the earth, for ever.

If the bowl were carried feveral miles above the earth, and there projected in a horizontal direction, with fuch a velocity as would make it move more than a femidiameter of the earth, in the time it would take to fall to the earth by gravity; in that cafe, and if there were no refifting medium in the way, the bowl would not fall to the earth at all; but would continue to circulate round it, keeping always in the fame tract, and returning to the fame point from which it was projected, with the fame velocity as at first. In this manner the moon goes round the earth, although fhe be as unactive and dead as any Itone upon it.

The third property of matter is mobility; for Mobility. we find that all matter is capable of being moved, if a fufficient degree of force be applied to overcome its inactivity or refiftance.

The fourth property of matter is divisibility, Divisibiof which there can be no end. For, fince matter lity. can never be annihilated by cutting or breaking, we can never imagine it to be cut into fuch fmall particles, but that if one of them be laid on a table, the uppermost fide of it will be further from the table than the undermost fide. Moreover, it would be abfurd to fay that the greatest mountain on earth has more halves, quarters, or tenth parts, than the fmallest particle of matter has.

We have many furprifing inftances of the fmallnefs to which matter can be divided by art: of which the two following are very remarkable.

3

I. If

1. If a pound of filver be melted with a fingle grain of gold, the gold will be equally diffuted through the whole filver; fo that taking one grain from any part of the mass (in which there can be no more than the 5760th part of a grain of gold) and diffolving it in *aqua fortis*, the gold will fall to the bottom.

2. The gold beaters can extend a grain of gold into a leaf containing 50 fquare inches; and this leaf may be divided into 500000 vilible parts. For an inch in length can be divided into 100 parts, every one of which will be visible to the bare eye: confequently a fquare inch can be divided into 10000 parts, and 50 fquare inches into 500000. And if one of these parts be viewed with a microfcope that magnifies the diameter of an object only 10 times, it will magnify the area 100 times; and then the 100th part of a 50000th part of a grain (that is, the 50 millionth part) will be vifible. Such leaves are commonly used in gilding; and they are fo very thin, that if 124500 of them were laid upon one another, and preffed together, they would not exceed one inch in thicknefs.

Yet all this is nothing in comparison of the lengths that nature goes in the division of matter. For Mr. Leewenboek tells us, that there are more animals in the milt of a fingle cod-fifh, than there are men upon the whole carth : and that, by comparing these animals in a microscope with grains of common fand, it appeared that one fingle grain is bigger than four millions of them. Now each animal must have a heart, arteries, veins, muscles, and nerves, otherwise they could neither live nor move. How inconceivably finall then must the particles of their blood be, to circulate through the fmallest ramifications

J. Mynde fc.

fications and joinings of their arteries and yeins? It has been found by calculation, that a particle of their blood must be as much fmaller than a globe of the tenth part of an inch in diameter, as that globe is fmaller than the whole earth; and yet, if these particles be compared with the particles of light, they will be found to exceed them as much in bulk as mountains do fingle grains of fand. For, the force of any body ftriking against an obstacle is directly in proportion to its quantity of matter multiplied into its velocity : and fince the velocity of the particles of light is demonstrated to be at least a million times greater than the velocity of a cannon-ball, it is plain, that if a million of thefe particles were as big as a fingle grain of fand, we durft no more open our eyes to the light, than we durft expose them to fand thot pointblank from a cannon.

That matter is infinitely divifible, in a mathe- Plate I. matical fenfe, is eafy to be demonstrated. For, Fig. 1. let AB be the length of a particle to be divided; and let it be touched at oppofite ends by the parallel lines CD and EF, which, suppose to be infinitely extended beyond D and F. Set off the equal divisions BG, GH, HI, &c. on the The infiline EF, towards the right hand from B; and fibility of take a point, as at R, any where toward the left matter hand from A, in the line CD: Then, from this proved. point, draw the right lines RG, RH, RI, &c. each of which will cut off a part from the particle AB. But after any finite number of fuch lines are drawn, there will ftill remain a part, as AP, at the top of the particle, which can never be cut off: because the lines DR and EF being parallel, no line can ever be drawn from the point R to any point of the line EF that will B 2 coincide

coincide with the line RD. Therefore the particle AB contains more than any finite number of parts.

Attrac-

6

A fifth property of matter is attraction, which feems rather to be infufed than inherent. Of this there are four kinds, viz. cohefion, gravitation, magnetifm, and cleffricity.

Cohefion.

The attraction of cohefion is that by which the finall parts of matter are made to flick and cohere together. Of this we have feveral inflances, fome of which follow.

1. If a fmall glafs tube, open at both ends, be dipt in water, the water will rife up in the tube to a confiderable height above its level in the bafon : which must be owing to the attraction of a ring of particles of the glass all round in the tube, immediately above those to which the water at any inftant riles. And when it has rifen to high, that the weight of the column balances the attraction of the tube, it rifes no higher. This can be no ways owing to the preffure of the air upon the water in the bason; for, as the tube is open at top, it is full of air above the water, which will prefs as much upon the water in the tube as the neighbouring air does upon any column of an equal diameter in the bason. Befides, if the fame experiment be made in an exhausted receiver of the air-pump, there will be found no difference,

2. A piece of loaf-fugar will draw up a fluid, and a fpunge will draw in water : and on the fame principle fap afcends in trees.

3. If two drops of quickfilver be placed near each other, they will run together and become one large drop.

4. If two pieces of lead be fcraped clean, and preffed together with a twift, they will attract each

each other fo ftrongly, as to require a force much greater than their own weight to feparate them. And this cannot be owing to the preffure of the air, for the fame thing will hold in an exhaufted receiver.

5. If two polifhed plates of marble or brafs be put together, with a little oil between them to fill up the pores in their furfaces, and prevent the lodgement of any air; they will cohere fo ftrongly, even if fufpended in an exhaufted receiver, that the weight of the lower plate will not be able to feparate it from the upper one. In putting thefe plates together, the one fhould be rubbed upon the other, as a joiner does two pieces of wood when he glues them.

6. If two pieces of cork, equal in weight, be put near each other in a bafon of water, they will move equally faft toward each other with an accelerated motion, until they meet: and then, if either of them be moved, it will draw the other after it. If two corks of unequal weights be placed near each other, they will approach with accelerated velocities inverfely proportionate to their weights: that is, the lighter cork will move as much fafter than the heavier, as the heavier exceeds the lighter in weight. This fhews that the attraction of each cork is in direct proportion to its weight or quantity of matter.

This kind of attraction reaches but to a very fmall diftance; for, if two drops of quickfilver be rolled in duft, they will not run together, becaufe the particles of duft keep them out of the fphere of each other's attraction.

Where the fphere of attraction ends, a repul- Repulfive force begins; thus, water repels most bodies fion. till they are wet; and hence it is, that a fmall

B 3

needle.

needle, if dry, fwims upon water; and flies walk upon it without wetting their feet.

The repelling force of the particles of a fluid is but finall; and therefore, if a fluid be divided, it easily unites again. But if glafs, or any other hard fubftance, be broke into finall parts, they cannot be made to flick together again without being first wetted: the repulsion being too great to admit of a re-union.

The repelling force between water and oil is fo great, that we find it almost impossible to mix them fo, as not to feparate again. If a ball of light wood be dipt in oil, and then put into water, the water will recede fo as to form a channel of fome depth all around the ball.

The repulsive force of the particles of air is fo great, that they can never be brought fo near togather by condensation as to make them flick or cohere. Hence it is, that when the weight of the incumbent atmosphere is taken off from any small quantity of air, that quantity will diffuse itfelf fo as to occupy (in comparison) an infinitely greater portion of space than it did before.

Attraction of gravitation is that power by which diffant bodies tend towards one another. Of this we have daily inflances in the falling of bodies to the earth. By this power in the earth it is, that bodies, on whatever fide, fall in lines perpendicular to its furface; and confequently, on opposite fides, they fall in opposite directions; all towards the center, where the force of gravity is as it were accumulated : and by this power it is, that bodies on the earth's furface are kept to it on all fides, fo that they cannot fall from it. And as it acts upon all bodies in proportion to their respective quantities of matter, without any regard to their bulks or figures,

Gravita-

figures, it accordingly conflitutes their weight. Hence,

If two bodies which contain equal quantities of matter, were placed at ever fo great a diftance from one another, and then left at liberty in free foace; if there were no other bodies in the univerfe to affect them, they would fall equally fwift towards one another by the power of gravity, with velocities accelerated as they approached each other; and would meet in a point which was half-way between them at first. Or, if two bodies, containing unequal quantities of matter, were placed at any diftance, and left in the fame manner at liberty, they would fall towards one another with velocities which would be in an inverse proportion to their respective quantities of matter; and moving faster and faster in their mutual approach, would at last meet in a point as much nearer to the place from which the heavier body began to fall, than to the place from which the lighter body began to fall, as the quantity of matter in the former exceeded that in the latter.

All bodies that we know of have gravity or weight. For, that there is no fuch thing as pofitive levity, even in fmoke, vapours, and fumes, is demonstrable by experiments on the airpump; which shews, that although the source of a candle ascends to the top of a tall receiver when full of air, yet, upon the air's being exhausted out of the receiver, the source falls down to the bottom of it. So, if a piece of wood be immersed in a jar of water, the wood will rise to the top of the water, because it has a less degree of weight than its bulk of water has: but if the jar be emptied of water, the wood falls to the bottom.

B 4

Aa

Gravity demonilrated to quantity

As every particle of matter has its proper gravity, the effect of the whole must be in probe as the portion to the number of the attracting particles : that is, as the quantity of matter in the whole of matter body. This is demonstrable by experiments on in bodies. pendulums; for, if they are of equal lengths, whatever their weights be, they vibrate in equal times. Now it is plain, that if one be double or triple the weight of another, it must require a double or triple power of gravity to make it move with the fame celerity : just as it would require a double or triple force to project a bullet of twenty or thirty pounds weight with the fame degree of fwiftneis that a bullet of ten pounds would require. Hence it is evident. that the power or force of gravity is always proportional to the quantity of matter in bodies. whatever their bulks or figures are.

It deof the diffance increafes.

Gravity alfo, like all other virtues or emanacreates as tions which proceed or iffue from a center, dethe fquare creafes as the diffance multiplied by itfelf increafes : that is, a body at twice the diftance of another, attracts with only a fourth part of the .force; at thrice the diffance, with a ninth part; at four times the diffance, with a fixteenth part; and fo on. This too is confirmed by comparing the diftance which the moon falls in a minute, from a right line touching her orbit, with the diftance through which heavy bodies near the earth fall in that time. And also by comparing the forces which retain Jupiter's moons in their orbits, with their refpective diffances from Jupiter. These forces will be explained in the next lecture.

> The velocity which bodies near the earth acquire in defcending freely by the force of gravity, is proportional to the times of their defcent. For,

For, as the power of gravity does not confift in a fingle impulfe, but is always operating in a conftant and uniform manner, it must produce equal effects in equal times; and confequently in a double or triple time, a double or triple effect. And fo, by acting uniformly on the body, must accelerate its motion proportionably to the time of its defcent.

To be a little more particular on this fubject. let us fuppofe that a body begins to move with a celerity conftantly and gradually increasing, in fuch a manner, as would carry it through a mile in a minute; at the end of this fpace it will have acquired fuch a degree of celerity, as is fufficient to carry it two miles the next minute, though it should then receive no new impulse from the caufe by which its motion had been accelerated : but if the fame accelerating caufe continues, it will carry the body a mile farther; on which account, it will have run through four miles at the end of two minutes; and then it will have acquired fuch a degree of celerity as is fufficient to carry it through a double fpace in as much more time, or eight miles in two minutes, even though the accelerating force fhould act upon it no more. But this force ftill continuing to operate in an uniform manner, will again, in an equal time, produce an equal effect; and fo, by carrying it a mile further, caufe it to move through five miles the third minute; for, the celerity already acquired, and the celerity ftill acquiring, will have each its complete effect. Hence we learn, that if the body should move one mile the first minute, it would move three miles the fecond, five the third, feven the fourth, aine the fifth, and fo on in proportion,

And thus it appears, that the fpaces defcribed in fucceffive equal parts of time, by an uniformly accelerated motion, are always as the odd numbers I, 3, 5, 7, 9, &c. and confequently, the whole spaces are as the squares of the times, or of the last acquired velocities. For, the continued addition of the odd numbers yields the fquares of all numbers from unity upwards. Thus, I is the first odd number, and the square of 1 is 1: a is the fecond odd number, and this added to 1 makes 4, the fquare of 2; 5 is the third odd number, which added to 4 makes 9, the fquare of 2; and fo on for ever. Since, therefore, the times and velocities proceed evenly and conftantly as 1, 2, 3, 4, &c. but the fpaces defcribed in each equal times are as 1, 3, 5, 7, &c. it is evident that the fpace defcribed

In 1 minute will be --- 1 =fquare of 1 In 2 minutes - 1+3=4=fquare of 2 In 3 minutes - 1+3+5=9=fquare of 3 In4 minutes 1+3+5+7=16=fquare of 4, &c.

N. B. The character + fignifies more, and = equal.

The defcending velocity will give a power of equal afcent.

Fig. 2.

As heavy bodies are uniformly accelerated by the power of gravity in their defcent, it is plain that they muft be uniformly retarded by the fame power in their afcent. Therefore, the velocity which a body acquires by falling, is fufficient to carry it up again to the fame height from whence it fell: allowance being made for the refiftance of the air, or other medium in which the body is moved. Thus, the body Din rolling down the inclined plane AB will acquire fuch a velocity by the time it arrives at B, as

B, as will carry it up the inclined plane BC, almost to C; and would carry it quite up to C, if the body and plane were perfectly fmooth, and the air gave no refiftance .- So, if a pendulum were put into motion, in a space quite free of air, and all other refiftance, and had no friction on the point of fuspension, it would move for ever : for the velocity it had acquired in falling through the defcending part of the arc, would be still fufficient to carry it equally high in the afcending part thereof.

The center of gravity is that point of a body The cenin which the whole force of its gravity or weight ter of is united. Therefore, whatever fupports that gravity, point bears the weight of the whole body : and whilft it is supported, the body cannot fall; because all its parts are in a perfect equilibrium about that point.

An imaginary line drawn from the center of gravity of any body towards the center of the earth, is called the line of direction. In this line and line all heavy bodies descend, if not obstructed.

Since the whole weight of a body is united in tion. its center of gravity, as that center alcends or defcends, we must look upon the whole body to do fo too. But as it is contrary to the nature of heavy bodies to afcend of their own accord, or not to defcend when they are permitted; we may be fure that, unlefs the center of gravity be fupported, the whole body will tumble or fall. Hence it is, that bodies ftand upon their bafes when the line of direction falls within the bafe; for in this cafe the body cannot be made to fall without first raising the center of gravity higher than it was before. Thus, the inclining body ABCD, whole center of gravity is E, Fig. 3. ftands firmly on its bale CDIK, because the line of

of direc-

14

of direction EF falls within the bafe. But if a weight, as ABGH, be laid upon the top of the body, the center of gravity of the whole body and weight together is raifed up to I; and then, as the line of direction ID falls without the bafe at D, the center of gravity I is not fupported; and the whole body and weight tumble down together.

Hence appears the abfurdity of people's rifing haftily in a coach or boat when it is likely to overfet: for, by that means they raife the center of gravity for far as to endanger throwing it quite out of the bafe; and if they do, they overfet the vehicle effectually. Whereas, had they clapt down to the bottom, they would have brought the line of direction, and confequently the center of gravity, farther within the bafe, and by that means might have faved themfelves.

The broader the bafe is, and the nearer the line of direction is to the middle or center of it, the more firmly does the body ftand. On the contrary, the narrower the bafe, and the nearer the line of direction is to the fide of it, the more eafily may the body be overthrown, a lefs change of polition being fufficient to remove the line of direction out of the bafe in the latter cafe than in the former. And hence it is, that a fphere is fo eafily rolled upon a horizontal plane; and that it is fo difficult, if not imposfible, to make things which are fharp-pointed to ftand upright on the point .- From what hath been faid, it plainly appears that if the plane be inclined on which the heavy body is placed, the body will flide down upon the plane whilft the line of direction falls within the bale; but it will tumble or roll down when that line falls without the

the bafe. Thus, the body A will only flide Fig. 4. down the inclined plane CD, whilft the body B rolls down upon it.

When the line of direction falls within the bafe of our feet, we ftand ; and moft firmly when it is in the middle: but when it is out of that bafe, we immediately fall. And it is not only pleafing, but even furprifing, to reflect upon the various and unthought-of methods and poftures which we use to retain this polition, or to recover it when it is loft. For this purpofe we bend our body forward when we rife from a chair, or when we go up flairs : and for this purpose a man leans forward when he carries a burden on his back, and backward when he carries it on his breaft; and to the right or left fide as he carries it on the oppofite fide. A thoufand more inftances might be added.

The quantity of matter in all bodies is in exact proportion to their weights, bulk for bulk. Therefore, heavy bodies are as much more denie or compact than light bodies of the fame bulk, as they exceed them in weight.

All bodies are full of pores, or fpaces void of All bodies matter: and in gold, which is the heavieft of porous. all known bodies, there is perhaps a greater quantity of fpace than of matter. For the particles of heat and magnetifm find an eafy paffage through the pores of gold; and even water itfelf has been forced through them. Befides, if we confider how eafily the rays of light pafs through fo folid a body as glafs, in all manner of directions, we fhall find reafon to believe that bodies are much more porous than is generally imagined.

All bodies are fome way or other affected by The exheat; and all metallic bodies are expanded in metals.

length,

8
Of the Properties of Matter.

length, breadth, and thickneis thereby.—The proportion of the expansion of feveral metals, according to the best experiments I have been able to make with my pyrometer, is nearly thus: Iron and steel as 3, copper 4 and an half, brass 5, tin 6, lead 7. An iron rod 3 feet long is about one 70th part of an inch longer in fummer than in winter.

The pyrometer.

Fig. 5.

The pyrometer here mentioned being (for aught I know) of a new conftruction, a defcription of it may perhaps be agreeable to the reader.

AA is a flat piece of mahogany, in which are fixed four brass studs B, C, D, L; and two pins. one at F and the other at H. On the pin F turns the crooked index E I, and upon the pin H the ftraight index GK, against which a piece of watch-fpring R bears gently, and fo preffes it towards the beginning of the scale MN. over which the point of that index moves. This fcale is divided into inches and tenth parts of an inch : the first inch is marked 1000, the second 2000, and fo on. A bar of metal O is laid into notches in the top of the fluds C and D; one end of the bar bearing against the adjusting forew P, and the other end against the crooked index E1, at a 20th part of its length from its center of motion F .- Now it is plain, that however much the bar O lengthens, it will move that part of the index EI, against which it bears, just as far: but the crooked end of the fame index, near H, being 20 times as far from the center of motion F as the point is against which the bar bears, it will move 20 times as far as the bar lengthens. And as this crooked end bears against the index GK at only a 20th part of the whole length GS from its center of motion

Of the Properties of Matter.

motion H, the point S will move through 20 times the fpace that the point of bearing near Hdoes. Hence, as 20 multiplied by 20 produces 400, it is evident that if the bar lengthens but a sooth part of an inch, the point S will move a whole inch on the fcale; and as every inch is divided into 10 equal parts, if the bar lengthens but the 10th part of the 400th part of an inch, which is only the 4000th part of an inch, the point S will move the tenth part of an inch, which is very perceptible.

To find how much a bar lengthens by heat, first lay it cold into the notches of the studs, and turn the adjusting forew P until the fpring Rbrings the point S of the index GK to the beginning of the divisions of the scale at M: then, without altering the fcrew any farther, take off the bar and rub it with a dry woollen cloth till it feels warm; and then, laying it on where it was, observe how far it pushes the point S upon the scale by means of the crooked index EI; and the point S will fhew exactly how much the bar has lengthened by the heat of rubbing. As the bar cools, the fpring R bearing against the index KG, will caufe its point S to move gradually back towards M in the fcale : and when the bar is quite cold, the index will reft at M. where it was before the bar was made warm by rubbing. The indexes have fmall rollers under them at I and K; which, by turning round on the fmooth wood as the indexes move, make their motions the eafier, by taking off a great part of the friction, which would otherwife be on the pins F and H, and of the points of the indexes themfelves on the wood.

Befides the universal properties above men- Magnetioned, there are bodies which have properties tilm.

17

peculiar

Of the Properties of Matter,

peculiar to themfelves: fuch as the loadstone, in which the most remarkable are these: I. It attracts iron and steel only. 2. It constantly turns one of its sides to the north and another to the fouth, when suffered by a thread that does not twist. 3. It communicates all its properties to a piece of steel when rubbed upon it, without losing any itself.

According to Dr. Helfham's experiments, the attraction of the loadstone decreases as the square of the diftance increases. Thus, if a loadstone be fuspended at one end of a balance, and counterpoifed by weights at the other end, and a flat piece of iron be placed beneath it, at the distance of four tenths of an inch, the stone will immediately defcend and adhere to the iron. But if the ftone be again removed to the fame diftance, and as many grains be put into the fcale at the other end as will exactly counterbalance the attraction, then, if the iron be brought twice as near the ftone as before, that is, only two tenth parts of an inch from it, there mult be four times as many grains put into the fcale as before, in order to be a just counterbalance to the attractive force, or to hinder the ftone from defcending and adhering to the iron. So, if four grains will do in the former cafe, there must be fixteen in the latter. But from fome later experiments, made with the greateft accuracy, it is found that the force of magnetifin decreases in a ratio between the reciprocal of the fquare and the reciprocal of the cube of the diftance; approaching to the one or the other, as the magnitudes of the attracting bodies are varied.

Elect: icity. Several bodies, particularly amber, glass, jet, fealing-wax, agate, and almost all precious stones, have a peculiar property of attracting and

and repelling light bodies when heated by rubbing. This is called electrical attraction, in which the chief things to be observed are, I. If a glass tube about an inch and a half diameter. and two or three feet long, be heated by 'rubbing, it will alternately attract and repel all light bodies when held near them. 2. It does not attract by being heated without rubbing. 3. Any light body being once repelled by the tube, will never be attracted again till it has touched fome other body. 4. If the tube be rubbed by a moift hand, or any thing that is wet, it totally deftroys the electricity. 5. Any body, except air, being interposed, ftops the electricity. 6. The tube attracts ftronger when rubbed over with bees-wax, and then with a dry woollen-cloth, 7. When it is well rubbed, if a finger be brought near it, at about the diftance of half an inch, the effluvia will inap against the finger, and make a little crackling noife; and if this be performed in a dark place, there will appear a little flash of light.

LECT. II.

Of central Forces.

X7E have already mentioned it as a necef- All bodies V fary confequence arifing from the dead- equally inhels or inactivity of matter, that all bodies different to motion endeavour to continue in the flate they are in, or reft. whether of reft or motion. If the body A were Plate II. placed in any part of free space, and nothing Fig. 1. either drew or impelled it any way, it would for ever remain in that part of fpace, because it could have no tendency of itfelf to remove any way from thence. If it receives a fingle impulie

IQ

pulfe any way, as fuppofe from A towards B, it will go on in that direction; for, of itfelf, it could never fwerve from a right line, nor ftop its courfe.—When it has gone through the fpace AB, and met with no refiftance, its velocity will be the fame at B at it was at A: and this velocity, in as much more time, will carry it through as much more fpace, from B to C; and fo on for ever. Therefore, when we fee a body in motion, we conclude that fome other fubftance muft have given it that motion; and when we fee a body fall from motion to reft, we conclude that fome other body or caufe ftopt it.

All motion naturally rectilineal.

As all motion is naturally rectilineal, it appears, that a bullet projected by the hand, or thot from a cannon, would for ever continue to move in the fame direction it received at first, if no other power diverted its courfe. Therefore when we fee a body move in a curve of any kind whatever, we conclude it must be asted upon by two powers at leaft; one putting it in motion, and another drawing it off from the rectilineal courfe it would otherwife have continued to move in : and whenever that power, which bent the motion of the body from a ftraight line into a curve, ceafes to act, the body will again move on in a ftraight line touching that point of the curve in which it was when the action of that power cealed. For example, a pebble moved round in a fling ever fo long a time, will fly off the moment it is fet at liberty, by flipping one end of the fling cord: and will go on in a line touching the circle it defcribed before : which line would actually be a ftraight one, if the earth's attraction did not affect the pebble, and bring it down to the ground. This flews that the natural tendency of the pebble, when put into

into motion, is to continue moving in a firaight line, although by the force that moves the fling it be made to revolve in a circle.

The change of motion produced is in propor-The eftion to the force impressed : for the effects of fects of natural caufes are always proportionate to the forces. force or power of those causes.

By these laws it is easy to prove that a body will defcribe the diagonal of a iquare or parallelogram, by two forces conjoined, in the fame time that it would defcribe either of the fides, by one force fingly. Thus, fuppofe the body A to reprefent a fhip at fea; and that it is Fig. 2. driven by the wind, in the right line AB, with fuch a force as would carry it uniformly from A to B in a minute: then suppose a stream or current of water running in the direction AD, with fuch a force as would carry the ship through an equal fpace from A to D in a minute. By thefe two forces, acting together at right angles to each other, the ship will defcribe the line AEC in a minute: which line (because the forces are equal and perpendicular to each other) will be the diagonal of an exact fquare. To confirm this law by an experiment, let there be a wooden fquare ABCD fo contrived, as to have the part Fig. 3. BEFC made to draw out or push into the square at pleafure. To this part let the pully H be joined, fo as to turn freely on an axis, which will be at H when the piece is pushed in, and at b when it is drawn out. To this part let the ends of a ftraight wire k be fixed, fo as to move along with it, under the pulley; and let the ball G be made to flide eafily on the wire. A thread m is fixed to this ball, and goes over the pulley to I; by this thread the ball may be drawn up on the wire, parallel to the fide AD, when the parc

C 2

part BEFC is pushed as far as it will go into the fquare. But, if this part be drawn out, it will carry the ball along with it, parallel to the bottom of the fquare DC. By this means, the ball G may either be drawn perpendicularly upward by pulling the thread m, or moved horizontally along by pulling out the part BEFC, in equal times, and through equal fpaces; each power acting equally and feparately upon it. But if, when the ball is at G, the upper end of the thread be tied to the pin I, in the corner A of the fixed fquare, and the moveable part BEFG be drawn out, the ball will then be acted upon by both the powers together: for it will be drawn up by the thread towards the top of the fquare, and at the fame time be carried with its wire k towards the right hand BC, moving all the while in the diagonal line L; and will be found at g when the fliding part is drawn out as far as it was before; which then will have caufed the thread to draw up the ball to the top of the infide of the fquare, just as high as it was before, when drawn up fingly by the thread without moving the fliding part.

If the acting forces are equal, but at oblique angles to each other, fo will the fides of the parallelogram be: and the diagonal run through by the moving body will be longer or fhorter, according as the obliquity is greater or finaller. Thus, if two equal forces act conjointly upon the body A, one having a tendency to move it through the fpace AB in the fame time that the other has a tendency to move it through an equal fpace AD; it will defcribe the diagonal AGCin the fame time that either of the fingle forces would have caufed it to defcribe either of the fides. If one of the forces be greater than the 2 other,

Fig. 4.

other, then one fide of the parallelogram will be fo much longer than the other. For, if one force fingly would carry the body through the fpace AE, in the fame time that the other would have carried it through the fpace AD, the joint action of both will carry it in the fame time through the space AHF, which is the diagonal of the oblique parallelogram ADEF.

If both forces act upon the body in fuch a manner, as to move it uniformly, the diagonal defcribed will be a straight line; but if one of the forces acts in fuch a manner as to make the body move faster and faster, then the line defcribed will be a curve. And this is the cafe of all bodies which are projected in rectilineal directions, and at the fame time acted upon by the power of gravity; which has a conftant tendency to accelerate their motions in the direction wherein it acts.

From the uniform projectile motion of bodies in The laws ftraight lines, and the univerfal power of gravity of the or attraction, arifes the curvilineal motion of all planetary the heavenly bodies. If the body A be projected along the straight line AFH in open space, Fig. 5. where it meets with no refiftance, and is not drawn alide by any power, it will go on for ever with the fame velocity, and in the fame direction. But if, at the fame moment the projectile force is given it at A, the body S begins to attract it with a force duly adjusted*, and perpendicular to its motion at A, it will then be drawn from the ftraight line AFH, and forced

* To make the projectile force a just balance to the gravitating power, fo as to keep the planet moving in a circle. it must give fuch a velocity as the planet would acquire by gravity when it had fallen through half the femidiameter of that circle.

C 3

to revolve about S in the circle ATW; in the fame manner, and by the fame law, that a pebble is moved round in a fling. And if, when the body is in any part of its orbit (as suppose at K) a finaller body as L, within the fphere of attraction of the body K, be projected in the right line L M, with a force duly adjusted, and perpendicular to the line of attraction LK; then, the fmall body L will revolve about the large body K in the orbit NO, and accompany it in its whole course round the yet larger body S. But then, the body K will no longer move in the circle ATW; for that circle will now be defcribed by the common center of gravity between K and L. Nay, even the great body S will not keep in the center; for it will be the common center of gravity between all the three bodies S, K, and L, that will remain immoveable there. So, if we suppose S and K connected by a wire P that has no weight, and K and Lconnected by a wire g that has no weight, the common center of gravity of all these three bodies will be a point in the wire P near S; which point being fupported, the bodies will be all in equilibrio as they move round it. Though indeed, firicitly speaking, the common center of gravity of all the three bodies will not be in the wire P but when thefe bodies are all in the right line. Here, S may represent the fun, K the earth, and L the moon.

In order to form an idea of the curves defcribed by two bodies revolving about their common center of gravity, whilft they themfelves with a third body are in motion round the common center of gravity of all the three; let See Plate us first suppose E to be the fun, and e the carth going round him without any moon; and their

III.

their moving forces regulated as above. In this cafe, whilft the earth goes round the fun in the dotted circle RTUWX, &c. the fun will The go round the circle ABD, whole center C is curves dethe common center of gravity between the fun feribed by and earth : the right line B & reprefenting the volving mutual attraction between them, by which they about are as firmly connected as if they were fixed at their the two ends of an iron bar ftrong enough to common hold them. So, when the earth is at e, the gravity. fun will be at E; when the earth is at T, the fun will be at F; and when the earth is at g, the fun will be at G. &c.

Now, let us take in the moon q (at the top of the figure) and fuppofe the earth to have no progreffive motion about the fun; in which cafe, whill the moon revolves about the earth in her orbit ABCD, the earth will revolve in the circle S 13, whofe center R is the common center of gravity of the earth and moon ; they being connected by the mutual attraction between them in the fame manner as the earth and fun are.

But the truth is, that whilft the moon revolves about the earth, the earth is in motion about the fun: and now, the moon will caufe the earth to defcribe an irregular curve, and not a true circle, round the fun; it being the common center of gravity of the earth and moon that will then deferibe the fame circle which the earth would have moved in, if it had not been attended by a moon. For, fuppoling the moon to defcribe a quarter of her progressive orbit about the earth in the time that the earth moves from e to f; it is plain, that when the earth comes to f, the moon will be found at r; in which time, their common center of gravity will C A

will have defcribed the dotted arc $R ext{ 1 } T$, the earth the curve $R ext{ 5 } f$, and the moon the curve $q ext{ 14 } r$. In the time that the moon defcribes another quarter of her orbit, the center of gravity of the earth and moon will defcribe the dotted arc $T ext{ 2 } U$, the earth the curve $f ext{ 6 } g$, the moon the curve $r ext{ 15 } s$, and fo on—And thus, whilf the moon goes once round the earth in her progreffive orbit, their common center of gravity defcribes the regular portion of a circle $R ext{ 1 } T ext{ 2 } U ext{ 3 } V ext{ 4 } W$, the earth the irregular curve $R ext{ 5 } f ext{ 6 } g ext{ 7 } b ext{ 8 } i$, and the moon the yet more irregular curve $q ext{ 14 } r ext{ 15 } s ext{ 16 } t ext{ 17 } u$; and then, the fame kind of tracks over again.

The center of gravity of the earth and moon is 6000 miles from the earth's center towards the moon; therefore the circle S_{13} which the earth defcribes round that center of gravity (in every courfe of the moon round her orbit) is 12000 miles in diameter. Confequently the earth is 12,000 miles nearer the fun at the time of full moon than at the time of new. [See the earth at f and at b.]

To avoid confusion in fo finall a figure, we have fupposed the moon to go only twice and a half round the earth, in the time that the earth goes once round the fun: it being impossible to take in all the revolutions which the makes in a year, and to give a true figure of her path, unlefs we should make the femidiameter of the earth's orbit at least 95 inches; and then, the proportional femidiameter of the moon's orbit would be only a quarter of an inch.—For a true figure of the moon's path, I refer the reader to my treatife of aftronomy.

If the moon made any complete number of revolutions about the earth in the time that the earth

earth makes one revolution about the fun, the paths of the fun and moon would return into themfelves at the end of every year; and fo be the fame over again : but they return not into themfelves in lefs than 19 years nearly; in which time, the earth makes nearly 19 revolutions about the fun, and the moon 235 about the earth.

If the planet A be attracted towards the fun, Plate II. with fuch a force as would make it fall from A Fig. 5. to B, in the time that the projectile impulfe would have carried it from A to F, it will defcribe the arc AG by the combined action of these A double forces, in the fame time that the former would projectile have caufed it to fall from A to B, or the latter force ba-have caufied it from A to F. Due if the have carried it from A to F. But, if the projec- quadruple tile force had been twice as great, that is, fuch as power of would have carried the planet from A to H, in gravity. the fame time that now, by the fuppolition, it carries it only from A to F; the fun's attraction must then have been four times as strong as formerly, to have kept the planet in the circle ATW; that is, it must have been fuch as would have caufed the planet to fall from A to E, which is four times the diftance of A from B, in the time that the projectile force fingly would have carried it from A to H, which is only twice the diftance of A from F^* . Thus, a double projectile force will balance a quadruple power of gravity in the fame circle; as appears plain by the figure, and shall foon be confirmed by an experiment.

The whirling-table is a machine contrived for Plate IV. shewing experiments of this nature. A A is a Fig. 1. ftrong frame of wood, B a winch or handle

* Here the arcs AG, AI must be supposed to be very fmall; otherwife AE, which is equal to HI, will be more than quadruple to A B, which is equal to F G.

fixed

The whirling table defcribed. fixed on the axis C of the wheel D, round which is the catgut firing F, which alfo goes round the fmall wheels G and K, croffing between them and the great wheel D. On the upper end of the axis of the wheel G, above the frame, is fixed the round board d, to which the bearer MSX may be faftened occafionally, and removed when it is not wanted. On the axis of the wheel H is fixed the bearer NTZ: and it is eafy to fee that when the winch B is turned, the wheels and bearers are put into a whirling motion.

Each bearer has two wires, W, X, and Y, Z. fixed and fcrewed tight into them at the ends by nuts on the outfide. And when these nuts are unferewed, the wires may be drawn out in order to change the balls U and V, which flide upon the wites by means of brafs loops fixed into the balls, which keep the balls up from touching the wood below them. A ftrong filk line goes through each ball, and is fixed to it at any length from the center of the bearer to its end as occasion requires, by a nut-fcrew at the top of the ball; the fhank of the forew goes into the center of the ball, and preffes the line against the under fide of the hole that it goes through. -The line goes from the ball, and under a fmall pulley fixt in the middle of the bearer; then up through a focket in the round plate (fee S and T) in the middle of each bearer; then through a flit in the middle of the fquare top (O and P) of each tower, and going over a fmall pulley on the top, comes down again the fame way, and is at last fastened to the upper end of the focket fixt in the middle of the above mentioned round plate. These plates S and T have each four round holes near their edges for letting them flide

flide up and down upon the wires which make the corners of each tower. The balls and plates being thus connected, each by its particular line, it is plain that if the balls be drawn outward, or towards the ends M and N of their refpective bearers, the round plates S and T will be drawn up to the top of their respective towers O and P.

There are feveral brafs weights, fome of two ounces, fome of three, and fome of four, to be occasionally put within the towers O and P, upon the round plates S and T: each weight having a round hole in the middle of it, for going upon the fockets or axes of the plates, and is flit from the edge to the hole, for allowing it to be flipt over the aforefaid line which comes from each ball to its respective plate. (See Fig. 2.)

The experiments to be made by this machine are as follows :

I. Take away the bearer MX, and take the Fig. I. ivory ball a, to which the line or filk cord b is fastened at one end; and having made a loop on the other end of the cord, put the loop over a pin fixt in the center of the board d. Then, turning the winch B to give the board a whirling The promotion, you will fee that the ball does not imme- penfity of diately begin to move with the board, but, on keep the account of its inactivity, it endeavours to conti- flate it is nue in the flate of reft which it was in before. - in. Continue turning, until the board communicates an equal degree of motion with its own to the ball, and then turning on, you will perceive that the ball will remain upon one part of the board, keeping the fame velocity with it, and having no relative motion upon it, as is the cafe with every thing that lies loofe upon the planeforface of the earth, which having the motion of the earth communicated to it, never endeavours to remove from

matter to

from that place. But ftop the board fuddenly by hand, and the ball will go on, and continue to revolve upon the board, until the friction thereof ftops its motion : which fhews, that matter being once put into motion would continue to move for ever, if it met with no reliftance. In like manner, if a perfon ftands upright in a boat before it begins to move, he can ftand firm; but the moment the boat fets off, he is in danger of falling towards that place which the boat departs from : becaufe, as matter, he has no natural propenfity to move. But when he acquires the motion of the boat, let it be ever fo fwift, if it be fmooth and uniform, he will ftand as upright and firm as if he was on the plain fhore; and if the boat ftrikes againft any obstacle, he will fall towards that obstacle; on account of the propenfity he has, as matter, to keep the motion which the boat has put him into.

2. Take away this ball, and put a longer cord to it, which may be put down through the hollow axis of the bearer MX, and wheel G, and fix a weight to the end of the cord below the machine; which weight, if left at liberty, will draw the ball from the edge of the whirlingboard to its center.

Bodies orbits have a tendency to fly out of these orbits.

Draw off the ball a little from the center, and moving in turn the winch; then the ball will go round and round with the board, and will gradually fly off farther and farther from the center, and raife up the weight below the machine : which fhews that all bodies revolving in circles have a tendency to fly off from these circles, and must have fome power acting upon them from the center of motion, to keep them from flying off. Stop the machine, and the ball will continue to revolve for

for fome time upon the board; but as the friction gradually ftops its motion, the weight acting upon it will bring it nearer and nearer to the center in every revolution, until it brings it quite thither. This fhews, that if the planets met with any refiftance in going round the fun, its attractive power would bring them nearer and nearer to it in every revolution, until they fell upon it.

3. Take hold of the cord below the machine Bodies with one hand, and with the other throw the ball move upon the round board as it were at right angles fafter in fmall orto the cord, by which means it will go round bits than and round upon the board. Then observing in large with what velocity it moves, pull the cord be- ones. low the machine, which will bring the ball nearer to the center of the board, and you will fee that the nearer the ball is drawn to the center, the faster it will revolve; as those planets which are nearest the fun revolve faster than those which are more remote; and not only go round fooner, becaufe they defcribe fmaller circles, but even move faster in every part of their respective circles.

4. Take away this ball, and apply the bearer Their MX, whofe center of motion is in its middle at centrifuw, directly over the center of the whirling-board gal forces thewn. d. Then put two balls (V and U) of equal weights upon their bearing wires, and having fixed them at equal diftances from their refpective centers of motion w and x upon their filk cords, by the fcrew nuts, put equal weights in the towers O and P. Laftly, put the catgut ftrings E and F upon the grooves G and H of the fmall wheels, which being of equal diameters, will give equal velocities to the bearers above, when the winch B is turned: and the balls U and V will fly

Ay off towards M and N; and will raife the weights in the towers at the fame initant. This fhews, that when bodies' of equal quantities of matter revolve in equal circles with equal velocities, their centrifugal forces are equal.

5. Take away these equal balls, and instead of them, put a ball of fix ounces into the bearer MX, at a fixth part of the diftance $w \ge$ from the center, and put a ball of one ounce into the oppofite bearer, at the whole diftance x y, which is equal to w z from the center of the bearer; and fix the balls at these distances on their cords, by the ferew nuts at top; and then the ball U. which is fix times as heavy as the ball V, will be at only a fixth part of the diftance from its center of motion; and confequently will revolve in a circle of only a fixth part of the circumference of the circle in which V revolves. Now, let any equal weights be put into the towers, and the machine be turned by the winch; which (as the catgut ftring is on equal wheels below) will caufe the balls to revolve in equal times; but Vwill move fix times as fast as U, because it revolves in a circle of fix times its radius; and both the weights in the towers will rife at once. This fhews, that the centrifugal forces of revolving bodies (or their tendencies to fly off from the circles they defcribe) are in direct proportion to their quantities of matter multiplied into their respective velocities; or into their diffances from the centers of their respective circles. For, fuppoling U, which weighs fix ounces, to be two inches from its center of motion w, the weight multiplied by the diftance is 12 : and fuppofing V, which weighs only one ounce, to be 12 inches diftant from the center of motion x, the weight 1 ounce multiplied by the diffance 12 inches 13

is 12. And as they revolve in equal times, their velocities are as their diftances from the center, namely, as I to 6.

- If these two balls be fixed at equal distances from their respective centers of motion, they will move with equal velocities; and if the tower O has 6 times as much weight put into it as the tower P has, the balls will raife their weights exactly at the fame moment. This fhews that the ball U being fix times as heavy as the ball V, has fix times as much centrifugal force, in defcribing an equal circle with an equal velocity.

6. If bodies of equal weights revolve in equal A double circles with unequal velocities, their centrifugal velocity forces are as the fquares of the velocities. To in the fame cirprove this law by an experiment, let two balls cle, is a U and V of equal weights be fixed on their cords balance at equal diftances from their respective centers to a quaof motion w and x; and then let the catgut power of ftring E be put round the wheel K (whole cir- gravity. cumference is only one half of the circumference of the wheel H or G) and over the pulley s to keep it tight; and let four times as much weight be put into the tower P, as in the tower O. Then turn the winch B_1 , and the ball V will revolve twice as fast as the ball U in a circle of the lame diameter, because they are equidistant from the centers of the circles in which they revolve; and the weight in the towers will both rife at the fame inftant, which fhews that a double velocity in the fame circle will exactly balance a quadruple power of attraction in the center of the circle. For the weights in the towers may be confidered as the attractive forces in the centers, acting upon the revolving balls; which, moving

duple

moving in equal circles, is the fame thing as if they both moved in one and the fame circle.

Kepler's Problem.

7. If bodies of equal weights revolve in unequal circles, in fuch a manner that the iquares of the times of their going round are as the cubes of their diffances from the centers of the circles they defcribe; their centrifugal forces are inverfely as the fourres of their diftances from those centers. For, the catgut ftring remaining as in the laft experiment, let the diftance of the ball V from the center x be made equal to two of the crofs divisions on its bearer; and the diftance of the ball U from the center w be three and a fixth part; the balls themfelves being of equal weights, and V making two revolutions by turning the winch, in the time that U makes one: fo that if we suppose the ball V to revolve in one fecond, the ball U will revolve in two feconds, the fquares of which are one and four : for the fquare of 1 is only 1, and the fquare of 2 is 4; therefore the fquare of the period or revolution of the ball V, is contained four times in the fquare of the period of the ball U. But the diftance of V is 2, the cube of which is 8_{*} and the diffance of U is $3\frac{1}{6}$, the cube of which is 32 very nearly, in which 8 is contained four times; and therefore, the fquares of the periods of V and U are to one another as the cubes of their diftances from x and w, which are the centers of their respective circles. And if the weight in the tower O be four ounces, equal to the square of 2, the distance of V from the center x; and the weight in the tower P be 10 ounces, nearly equal to the fquare of 3t, the diftance of U from w; it will be found upon turning the machine by the winch, that the balls U and V will raife their respective weights at the

the fame inftant of time. Which confirms that famous observation of KEPLER, viz. That the Iquares of the times in which the planets go round the fun are in the fame proportion as the cubes of their diftances from him; and that the fun's attraction is inverfely as the fquare of the diftance from his center : that is, at twice the diffance, his attraction is four times lefs; and thrice the distance, nine times lefs; at four times the diftance, fixteen times lefs; and fo on, to the remoteft part of the fyftem.

8. Take off the catgut ftring E from the great wheel D and the fmall wheel H, and let the ftring F remain upon the wheels D and G. Take away also the bearer MX from the whirling-board d, and inftead thereof put the machine AB upon it, fixing this machine to the center of the board by the pins c and d, in fuch Fig. 3. a manner, that the end ef may rife above the board to an angle of 30 or 40 degrees. In the The abupper fide of this machine are two glafs tubes furdiny of a and b, close ftopt at both ends; and each the Cartetube is about three quarters full of water. In fian vorthe tube a is a little quickfilver, which naturally falls down to the end a in the water, becaufe It is heavier than its bulk of water; and in the tube b is a fmall cork which floats on the top of the water at e, becaufe it is lighter; and it is fmall enough to have liberty to rife or fall in the tube. While the board b with this machine upon it continues at reft, the quickfilver lies at the bottom of the tube a, and the cork floats on the water near the top of the tube b. But, upon turning the winch, and putting the machine in motion, the contents of each tube will fly off towards the uppermoft ends (which are farthest from the center of motion) the heaviest with

with the greatest force. Therefore the quickfilver in the tube a will fly off quite to the end f, and occupy its bulk of fpace there, excluding the water from that place, because it is lighter . than quickfilver; but the water in the tube b flying off to its higher end e, will exclude the cork from that place, and caufe the cork to defcend towards the lowermost end of the tube, where it will remain upon the loweft end of the water near b; for the heavier body having the greater centrifugal force, will therefore poffefs the uppermoft part of the tube; and the lighter body will keep between the heavier and the lowermost part.

This demonstrates the abfurdity of the Cartefian doctrine of the planets moving round the fun in vortexes: for, if the planet be more denfe or heavy than its bulk of the vortex, it will fly off therein, farther and farther from the fun; if lefs denfe, it will come down to the loweft part of the vortex, at the fun: and the whole vortex itfelf must be furrounded with fomething like a great wall, otherwife it would fly quite off, planets and all together .- But while gravity exifts, there is no occafion for fuch vortexes; and when it ceases to exift, a ftone thrown upwards will never return to the earth again.

If one body moves round another, move round mon center of gravity.

9. If a body be fo placed on the whirlingboard of the machine (Fig. 1.) that the center of gravity of the body be directly over the center of the board, and the board be put into ever fo them must rapid a motion by the winch B, the body will turn round with the board, but will not remove from the middle of it; for, as all parts of the their com- body are in equilibrio round its center of gravity, and the center of gravity is at reft in the center of motion, the centrifugal force of all parts of the I

the body will be equal at equal diffances from its center of motion, and therefore the body will remain in its place. But if the center of gravity be placed ever fo little out of the center of motion, and the machine be turned fwiftly round, the body will fly off towards that fide of the board on which its center of gravity lies. Thus, Fig. 4. if the wire C with its little ball B be taken away from the demi-globe A, and the flat fide ef of this demi-globe be laid upon the whirling board of the machine, fo that their centers may coincide; if then the board be turned ever fo quick by the winch, the demi-globe will remain where it was placed. But if the wire C be fcrewed into the demi-globe at d, the whole becomes one body, whole center of gravity is now at or near d. Let the pin c be fixed in the center of the whirling-board, and the deep groove b cut in the flat fide of the demi-globe be put upon the pin, fo as the pin may be in the center of A [See Fig. Fig. 5. 5. where this groove is reprefented at b] and let the whirling-board be turned hy the winch, which will carry the little ball B (Fig. 4.) with its wire C, and the demi-globe A, all round the center-pin c i; and then, the centrifugal force of the little ball B, which weighs only one ounce, will be fo great, as to draw off the demi-globe A, which weighs two pounds, until the end of the groove at e firikes against the pin c, and to prevents the demi-globe A from going any farther : otherwife, the centrifugal force of B would have been great enough to have carried A quite off the whirling-board. Which fhews, that if the fun were placed in the very center of the orbits of the planets, it could not poffibly remain there; for the centrifugal forces of the planets would carry them quite off, and the fun D 2

with

with them; especially when several of them happened to be in any one quarter of the heavens. For the fun and planets are as much connected by the mutual attraction that fubfifts between them, as the bodies A and B are by the wire C which is fixed into them both. And even if there were but one fingle planet in the whole heavens to go round ever fo large a fun in the center of its orbit, its centrifugal force would foon carry off both itself and the fun. For, the greatest body placed in any part of free space might be eafily moved : because if there were no other body to attract it, it could have no weight or gravity of itfelf; and confequently, though it could have no tendency of itfelf to remove from that part of fpace, yet it might be very eafily moved by any other fubftance.

10. As the centrifugal force of the light body B will not allow the heavy body A to remain in the center of motion, even though it be 24 times as heavy as B; let us now take the ball A (Fig. 6.) which weighs 6 ounces, and connect it by the wire C with the ball B, which weighs only one ounce; and let the fork E be fixed into the center of the whirling-board : then hang the balls upon the fork by the wire C in fuch a manndr, that they may exactly balance each other; which will be when the center of gravity between them, in the wire at d, is supported by the fork. And this center of gravity is as much nearer to the center of the ball A, than to the center of the ball B, as A is heavier than B, allowing for the weight of the wire on each fide of the fork. This done, let the machine be put into motion by the winch; and the balls A and B will go round their common center of gravity d, keeping their balance, because either will not allow the

39

the other to fly off with it. For, fuppoling the ball B to be only one ounce in weight, and the ball A to be fix ounces; then, if the wire C were equally heavy on each fide of the fork, the center of gravity d would be fix times as far from the center of the ball B as from that of the ball A, and confequently B will revolve with a velocity fix times as great as A does; which will give Bfix times as much centrifugal force as any fingle ounce of A has: but then, as B is only one ounce, and A fix ounces, the whole centrifugal force of A will exactly balance the whole centrifugal force of B: and therefore, each body will detain the other fo as to make it keep in its circle. This fhews that the fun and planets muft all move round the common center of gravity of the whole fyftem, in order to preferve that juft balance which takes place among them. For, the planets being as unactive and dead as the above balls, they could no more have put themfelves into motion than these balls can; nor have kept in their orbits without being balanced at first with the greatest degree of exactness upon their common center of gravity, by the Almighty hand that made them and put them in motion.

Perhaps it may be here afked, that fince the center of gravity between these balls must be supported by the fork E in this experiment, what prop it is that fupports the center of gravity of the folar fyftem, and confequently bears the weight of all the bodies in it; and by what is the prop itfelf fupported? The answer is easy and plain; for the center of gravity of our balls must be supported, because they gravitate towards the earth, and would therefore fall to it : but as the fun and planets gravitate only towards D 3 one

one another, they have nothing elfe to fail to; and therefore have no occafion for any thing to fupport their common center of gravity: and if they did not move round that center, and confequently acquire a tendency to fly off from it by their motions, their mutual attractions would foon bring them together; and fo the whole would become one mafs in the fun: which would alfo be the cafe if their velocities round the fun were not quick enough to create a centrifugal force equal to the fun's attraction.

But after all this nice adjustment, it appears evident that the Deity cannot withdraw his regulating hand from his works, and leave them to be folely governed by the laws which he has imprest upon them at first. For if he should once leave them fo, their order would in time come to an end; because the planets must neceffarily difturb one another's motions by their mutual attractions, when feveral of them are in the fame quarter of the heavens; as is often the cafe : and then, as they attract the fun more towards that quarter than when they are in a manner difperfed equably around him, if he was not at that time made to defcribe a portion of a larger circle round the common center of gravity, the balance would then be immediately deftroyed; and as it could never reftore itfelf again. the whole fystem would begin to fall together, and would in time unite in a mais at the fun .-Of this diffurbance we have a very remarkable. instance in the comet which appeared lately; and which, in going laft up before from the fun, went to near to Jupiter, and was fo affected by his attraction, as to have the figure of its orbit much changed; and not only fo, but to have its period altered.

altered, and its course to be different in the heavens from what it was last before.

11. Take away the fork and balls from the Fig. 7. whirling.board, and place the trough AB thereon, fixing its center to the center of the whirling-board by the pin H. In this trough are two balls D and E, of unequal weights, connected by a wire f; and made to flide eafly upon the wire C ftretched from end to end of the trough, and made fast by nut-fcrews on the outfide of the ends. Let these balls be fo placed upon the wire C, that their common center of gravity g may be directly over the center of the whirling-board, Then, turn the machine by the winch, ever fo fwiftly, and the troughand balls will go round their center of gravity, fo as neither of the balls will fly off; because, on account of the equilibrium, each ball detains the other with an equal force acting against it. But if the ball E be drawn a little more towards the end of the trough at A, it will remove the center of gravity towards that end from the center of motion; and then, upon turning the machine, the little ball E will fly off, and ftrike with a confiderable force against the end A, and draw the great ball B into the middle of the trough. Or, if the great ball D be drawn towards the end B of the trough, fo that the center of gravity may be a little towards that end from the center of motion, and the machine be turned by the winch, the great ball D will fly off, and strike violently against the end B of the trough, and will bring the little ball E into the middle of it. If the trough be not made very ftrong, the ball D will break through it.

12. The reason why the tides rife at the fame Of the abfolute time on opposite fides of the earth, and tides. D 4 confequently

confequently in oppofite directions, is made abundantly plain by a new experiment on the whirling table. The caufe of their rifing on the fide next the moon every one understands to be owing to the moon's attraction : but why they fhould rife on the opposite fide at the fame time, where there is no moon to attract them, is perhaps not fo generally underftood. For it would feem that the moon fhould rather draw the waters (as it were) closer to that fide, than raife them upon it, directly contrary to her attractive force. Let the circle abcd reprefent the earth, with its fide c turned toward the moon, which will then attract the waters fo, as to raife them from c to g. But the queftion is, why fhould they rife as high at that very time on the opposite fide, from a to e? In order to explain this, let there be a plate AB fixed upon one end of the flat bar DC; with fuch a circle drawn upon it as abcd (in Fig. 8.) to represent the round figure of the earth and fea; and fuch an ellipfis as efg k to reprefent the fwelling of the tide at e and g, occafioned by the influence of the moon. Over this plate AB let the three ivory balls e, f, g, be hung by the filk lines b, i, k, fastened to the tops of the crooked wires H, I, K, in fuch a manner, that the ball at e may hang freely over the fide of the circle e, which is fartheft from the moon M (at the other end of the bar); the ball at f may hang freely over the center, and the ball at g hang over the fide of the circle g, which is nearest the moon. The ball f may reprefent the center of the earth, the ball g fome water on the fide next the moon, and the ball e fome water on the opposite fide, On the back of the moon M is fixt the fhort bar N parallel to the horizon, and there are three holes in it above the little weights p, q, r. A filk

Fig. 8.

Fig. 9.

filk thread o is tied to the line k close above the ball g, and paffing by one fide of the moon M. goes through a hole in the bar N, and has the weight p hung to it. Such another thread n is tied to the line i, close above the ball f, and paffing through the center of the moon M and middle of the bar N, has the weight q hung to it, which is lighter than the weight p. A third thread m is tied to the line b, clote above the ball e, and paffing by the other fide of the moon M. through the bar N, has the weight r hung to it. which is lighter than the weight q.

The use of these three unequal weights is to represent the moon's unequal attraction at different diftances from her. With whatever force fhe attracts the center of the earth, fhe attracts the fide next her with a greater degree of force. and the fide farthest from her with a lefs. So. if the weights are left at liberty, they will draw all the three balls towards the moon with different degrees of force, and caufe them to make the appearance flewn in Fig. 10; by which Fig. 10. means they are evidently farther from each other than they would be if they hung at liberty by the lines b, i, k; becaufe the lines would then hang perpendicularly. This fhews, that as the moon attracts the fide of the earth which is nearest her with a greater degree of force than the does the center of the earth, fhe will draw the water on that fide more than fhe draws the center, and fo caufe it to rife on that fide: and as fhe draws the center more than the draws the oppofite fide, the center will recede farther from the furface of the water on that opposite fide, and fo leave it as high there as fhe raifed it on the fide next to her. For, as the center will be in the middle between the

Of the Tides.

a.A.

the tops of the opposite elevations, they must of course be equally high on both fides at the fame time.

But upon this fuppofition the earth and moon would foon come together : and to be fure they would, if they had not a motion round their common center of gravity, to create a degree of centrifugal force fufficient to balance their mutual attraction. This motion they have; for as the moon goes round her orbit every month, at the diftance of 240000 miles from the earth's center, and of 234000 miles from the center of gravity of the earth and moon, fo does the earth go round the fame center of gravity every month at the diftance of 6000 miles from it; that is. from it to the center of the earth. Now as the earth is (in round numbers) 8000 miles in diameter, it is plain that its fide next the moon is only 2000 miles from the common center of gravity of the earth and moon; its center 6000 miles diftant therefrom; and its farther fide from the moon 10000. Therefore the centrifugal forces of these parts are as 2000, 6000, and 10000; that is, the centrifugal force of any fide of the earth, when it is turned from the moon, is five times as great as when it is turned towards the moon. And as the moon's attraction (expreft by the numbers 6000) at the earth's center keeps the earth from flying out of this monthly circle, it must be greater than the centrifugal force of the waters on the fide next her ; and confequently, her greater degree of attraction on that fide is fufficient to raife them; but as her attraction on the opposite fide is lefs than the centrifugal force of the water there, the excess of this force is fufficient to raife the water just as high

The Earth's Motion demonstrated.

high on the oppofite fide .- To prove this expe- Fig. 9. rimentally, let the bar DC with its furniture be fixed upon the whirling-board of the machine (Fig. I.) by pushing the pin P into the center of the board ; which pin is in the center of gravity of the whole bar with its three balls e, f, g. and moon M. Now if the whirling-board and bar be turned flowly round by the winch, until the ball f hangs over the center of the circle, as in Fig. 11. the ball g will be kept towards the moon by the heaviest weight p, (Fig. 9.) and the ball e, on account of its greater centrifugal force, and the leffer weight r, will fly off as far to the other fide, as in Fig. 11. And fo, whilft the machine is kept turning, the balls e and g will hang over the ends of the ellipfis l f k. So that the centrifugal force of the ball e will exceed the moon's attraction just as much as her attraction exceeds the centrifugal force of the ball g, whilft her attraction just balances the centrifugal force of the ball f, and makes it keep in its circle. And hence it is evident that the tides must rife to equal heights at the fame time on opposite fides of the earth. This experiment, to the best of my knowledge, is entirely new.

From the principles thus effablished, it is The evident that the earth moves round the fun, and earth's not the fun round the earth; for the centrifugal motion law will never allow a great body to move round strated. a finall one in any orbit whatever; fpecially when we find that if a finall body moves round a great one, the great one must also move round the common center of gravity between them two. And it is well known that the quantity of matter in the fun is 227000 times as great as the quantity of matter in the earth. Now, as the fun's diffance
The Earth's Motion demonstrated.

46

Fig. 12.

diftance from the earth is at leaft $\$_{1,000,000}$ of miles, if we divide that diftance by 227,000, we fhall have only 357 for the number of miles that the center of gravity between the fun and earth is diftant from the fun's center. And as the fun's femidiameter is $\frac{1}{4}$ of a degree, which, at fo great a diftance as that of the fun, muft be no lefs than $3\$_{1500}$ miles, if this be divided by 357, the quotient will be $1068\frac{1}{2}$, which fhews that the common center of gravity between the fun and earth is within the body of the fun; and is only the $1068\frac{1}{2}$ part of his femidiameter from his center toward his furface.

All globular bodies, whole parts can yield, and which do not turn on their axes, must be perfect fpheres, because all parts of their furfaces are equally attracted toward their centers. But all fuch globes which do turn on their axes will be oblate fpheroids; that is, their furfaces will be higher, or farther from the center, in the equatoreal than in the polar regions. For, as the equatoreal parts move quickeft, they muft have the greatest centrifugal force; and will therefore recede farthelt from the axis of motion. Thus, if two circular hoops AB and CD, made thin and flexible, and croffing one another at right angles, be turned round their axis E F by means of the winch m, the wheel n. and pinion o, and the axis be loofe in the pole or interfection e, the middle parts A, B, C, D will fwell out fo as to ftrike against the fides of the frame at F and G, if the pole e, in finking to the pin E, be not ftopt by it from finking farther : fo that the whole will appear of an oval figure, the equatoreal diameter being confiderably longer than the polar. That our earth is of this figure, is demonstrable from actual meafurement

furement of fome degrees on its furface, which are found to be longer in the frigid zones than in the torrid : and the difference is found to be fuch as proves the earth's equatoreal diameter to be 36 miles longer than its axis .- Seeing then, the earth is higher at the equator than at the poles, the fea, which like all other fluids naturally runs downward (or towards the places which are nearest the earth's center) would run towards the polar regions, and leave the equatoreal parts dry, if the centrifugal force of the water, which carried it to those parts, and fo raifed them, did not detain and keep it from running back again towards the poles of the earth.

LECT. III.

Of the mechanical Powers.

F we confider bodies in motion, and com- The pare them together, we may do this either foundawith respect to the quantities of matter they tion of contain, or the velocities with which they are all memoved. The heavier any body is, the greater is the power required either to move it or to ftop its motion: and again, the fwifter it moves, the greater is its force. So that the whole momentum or quantity of force of a moving body is the refult of its quantity of matter multiplied by the velocity with which it is moved. And when the products arising from the multiplication of the particular quantities of matter in any two bodies by their respective velocities are equal, the momenta or intire forces are fo too. Thus, fuppofe a body, which we shall call A, to weigh 40 pounds, and to move at the rate of two miles 111

in a minute; and another body, which we fhall call B, to weigh only four pounds, and to move 20 miles in a minute; the entire forces with which these two bodies would strike against any obftacle would be equal to each other, and therefore it would require equal powers to ftop them. For 40 multiplied by 2 gives 80, the force of the body A: and 20 multiplied by 4 gives 80. the force of the body B.

Upon this eafy principle depends the whole of mechanics : and it holds univerfally true, that when two bodies are fufpended on any machine, fo as to act contrary to each other; if the machine be put into motion, and the perpendicular afcent of one body multiplied into its weight, be equal to the perpendicular defcent of the other body multiplied into its weight, those bodies, how unequal foever in their weights, will balance one another in all fituations : for, as the whole afcent of one is performed in the fame time with the whole defcent of the other, their respective velocities must be directly as the fpaces they move through; and the excels of weight in one body is compenfated by the excels of velocity in the other .- Upon this principle it is easy to compute the power of any mechanical the power engine, whether fimple or compound ; for it is but only finding how much fwifter the power moves than the weight does (i.e. how much farther in the fame time) and just fo much is the power increafed by the help of the engine.

> In the theory of this fcience, we suppose all planes perfectly even, all bodies perfectly imooth, levers to have no weight, cords to be extremely pliable, machines to have no friction; and in fhort, all imperfections must be fet alide until the

How to compute of any mechanical engine.

the theory be established; and then, proper allowances are to be made.

The fimple machines, ufually called mechanical The mepowers, are fix in number, viz. the lever, the chanic wheel and axle, the pulley, the inclined plane, the powers, wedge, and the fcrew.—They are called mechanical powers, becaufe they help us mechanically to raife weights, move heavy bodies, and overcome refiftances, which we could not effect without them.

1. A leter is a bar of iron or wood, one part The leof which being supported by a prop, all the ver. other parts turn upon that prop as their center of motion: and the velocity of every part or point is directly as its distance from the prop. Therefore, when the weight to be raifed at one end is to the power applied at the other to raife it, as the distance of the power from the prop is to the distance of the weight from the prop, the power and weight will exactly balance or counterpoise each other: and as a common lever has next to no friction on its prop, a very little additional power will be fufficient to raife the weight.

There are four kinds of levers. 1. The common fort, where the prop is placed between the weight and the power; but much nearer to the weight than to the power. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them. 4. The bended lever, which differs only in form from the first fort, but not in property. Those of the first and fecond kind are often used in mechanical engines; but there are few instances in which the third fort is used.

A Com-

The balance.

50

Plate V. Fig. 1. The first kind of lever.

A common balance is by fome reckoned a lever of the first kind; but as both its ends are at equal diftances from its center of motion, they move with equal velocities; and therefore, as it gives no mechanical advantage, it cannot properly be reckoned among the mechanical powers. A lever of the first kind is represented by the bar ABC, supported by the prop D. Its principal use is to loofen large ftones in the ground, or raife great weights to fmall heights, in order to have ropes put under them for raifing them higher by other machines. The parts AB and BC, on different fides of the prop D, are called the arms of the lever: the end A of the florter arm AB being applied to the weight intended to be raifed, or to the refiftance to be overcome, and the power applied to the end C of the longer arm BC.

In making experiments with this machine, the fhorter arm AB must be as much thicker than the longer arm BC, as will be fufficient to balance it on the prop. This supposed, let P reprefent a power, whole gravity is equal to I ounce, and W a weight, whole gravity is equal to 12 ounces. Then, if the power be 12 times as far from the prop as the weight is, they will exactly counterpoife; and a fmall addition to the power P will caufe it to defcend, and raife the weight W; and the velocity with which the power defcends will be to the velocity with which the weight rifes, as 12 to 1: that is, directly as their diftances from the prop; and confequently, as the fpaces through which they move. Hence, it is plain that a man, who by his natural ftrength, without the help of any machine, could fupport an hundred weight, will by the help of this lever be enabled to support twelve

twelve hundred. If the weight be lefs, or the power greater, the prop may be placed fo much farther from the weight; and then it can be raifed to a proportionably greater height. For univerfally, if the intenfity of the weight multiplied into its distance from the prop be equal to the intenfity of the power multiplied into its diftance from the prop, the power and weight will exactly balance each other; and a little addition to the power will raife the weight. Thus, in the prefent inftance, the weight W is 12 ounces, and its diftance from the prop is 1 inch ; and 12 multiplied by 1 is 12; the power P is equal to I ounce, and its diffance from the prop. is 12 inches, which multiplied by I is 12 again; and therefore there is an equilibrium between them. So, if a power equal to 2 ounces be applied at the diftance of 6 inches from the prop, it will just balance the weight W; for 6 multiplied by 2 is 12, as before. And a power equal to 3 ounces placed at 4 inches diftance from the prop would be the fame; for 3 times 4 is 12; and fo on, in proportion.

The statera or Roman steelyard is a lever of The steelthis kind, and is used for finding the weights of yard. different bodies by one fingle weight placed at different diffances from the prop or center of motion D. For, if a scale hangs at A, the extremity of the fhorter arm AB, and is of fuch a weight as will exactly counterpoife the longer arm BC; if this arm be divided into as many equal parts as it will contain, each equal to AB, the fingle weight P (which we may suppose to be I pound) will ferve for weighing any thing as heavy as itfelf, or as many times heavier as there are divisions in the arm BC, or any quantity between its own weight and that quantity. CAD As

As for example, if P be 1 pound, and placed at the first division I in the arm BC, it will balance I pound in the fcale at A: if it be removed to the fecond division at 2, it will balance 2 pounds in the fcale : if to the third, 3 pounds; and to on to the end of the arm BC. If each of these integral divisions be subdivided into as many equal parts as a pound contains ounces, and the weight P be placed at any of thefe fubdivisions, fo as to counterpoife what is in the fcale, the pounds and odd ounces therein will by that means be afcertained.

To this kind of lever may be reduced feveral forts of inftruments, fuch as fciffars, pinchers. inuffers; which are made of two levers acting contrary to one another : their prop or center of motion being the pin which keeps them together.

In common practice, the longer arm of this lever greatly exceeds the weight of the fhorter : which gains great advantage, becaufe it adds fo much to the power.

The feof lever.

Fig. 2.

A lever of the fecond kind has the weight cond kind between the prop and the power. In this, as well as the former, the advantage gained is as the diftance of the power from the prop to the diftance of the weight from the prop: for the respective velocities of the power and weight are in that proportion ; and they will balance each other when the intenfity of the power multiplied by its diftance from the prop is equal to the intenfity of the weight multiplied by its diftance from the prop. Thus, if AB be a lever on which the weight W of 6 ounces hangs at the diftance of 1 inch from the prop G, and a power P equal to the weight of 1 ounce hangs at the end B, 6 inches from the prop, by the cord CD

C D going over the fixed pulley E, the power will just support the weight: and a finall addition to the power will raife the weight, t inch for every 6 inches that the power defcends.

This lever fhews the reafon why two men carrying a burden upon a flick between them, bear unequal fhares of the burden in the inverse proportion of their diffances from it. For it is well known, that the nearer any of them is to the burden, the greater share he bears of it : and if he goes directly under it, he bears the whole. So, it one man be at G, and the other at P, having the pole or flick AB refling on their shoulders; if the burden or weight W be placed five times as near the man at G, as it is to the man at P, the former will bear five times as much weight as the latter. This is likewife applicable to the cafe of two horfes of unequal firength to be fo yoked, as that each horfe may draw a part proportionable to his ftrength; which is done by fo dividing the beam they pull, that the point of traction may be as much nearer to the fironger horfe than to the weaker, as the ftrength of the former exceeds that of the latter.

To this kind of lever may be reduced oars, rudders of fhips, doors turning upon hinges, cutting-knives which are fixed at the point of the blade, and the like.

If in this lever we fuppofe the power and The third weight to change places, fo that the power may kind of be between the weight and the prop, it will become a lever of the third kind : in which, that there may be a balance between the power and the weight, the intenfity of the power muft exceed the intenfity of the weight, juft as much as the diffance of the weight from the prop ex-E 2 cceeds

Fig. 3.

54

ceeds the diffances of the power from it. Thus, let E be the prop of the lever AB, and W a weight of I pound, placed 3 times as far from the prop, as the power P acts at F, by the cord C going over the fixed pulley D; in this cafe, the power muft be equal to three pounds, in order to fupport the weight.

To this fort of lever are generally referred the bones of a man's arm: for when we lift a weight by the hand, the mufcle that exerts its force to raife that weight, is fixed to the bone about one tenth part as far below the elbow as the hand is. And the elbow being the center round which the lower part of the arm turns, the mufcle muft therefore exert a force ten times as great as the weight that is raifed.

As this kind of lever is a difadvantage to the moving power, it is never ufed but in cafes of neceffity; fuch as that of a ladder, which being fixed at one end, is by the ftrength of a man's arms reared againft a wall. And in clock-work, where all the wheels may be reckoned levers of this kind, becaufe the power that moves every wheel, except the firft, acts upon it near the center of motion by means of a fmall pinion, and the refiftance it has to overcome, acts againft the teeth round its circumference.

The fourth kind of lever. Fig. 4. The fourth kind of lever differs nothing from the first, but in being bended for the fake of convenience. ACB is a lever of this fort, bended at C, which is its prop, or center of motion. P is a power acting upon the longer arm AC at F, by means of the cord DE going over the pulley G; and W is a weight or refistance acting upon the end B of the fhorter arm BC. If the power is to the weight, as C B is to C F, they are in equilibria. Thus, suppose W to be 5 pounds

pounds acting at the diffance of one foot from the center of motion C, and P to be I pound acting at F, five feet from the center C, the power and weight will juft balance each other. A hammer drawing a nail is a lever of this fort.

2. The fecond mechanical power is the robeel The and axle, in which the power is applied to the wheel and circumference of the wheel, and the weight is axle. raifed by a rope which coils about the axle as the wheel is turned round. Here it is plain that the velocity of the power must be to the velocity of the weight, as the circumference of the wheel is to the circumference of the axle: and confequently, the power and weight will balance each other, when the intenfity of the power is to the intenfity of the weight, as the cicumference of the axle is to the circumference of the wheel. Let AB be a wheel, CD its axle, and fuppofe Fig. 5. the circumference of the wheel to be 8 times as great as the circumference of the axle; then, a power P equal to I pound hanging by the cord I, which goes round the wheel, will balance a weight W of 8 pounds hanging by the rope K, which goes round the axle. And as the friction on the pivets or gudgeons of the axle is but fmall, a fmall addition to the power will caufe it to descend, and raife the weight : but the weight will rife with only an eighth part of the velocity wherewith the power defcends, and confequently, through no more than an eighth part of an equal space, in the fame time. If the wheel be pulled round by the handles S, S, the power will be increafed in proportion to their length. And by this means, any weight may be raifed as high as the operator pleafes.

E 3

To

To this fort of engine belong all cranes for raifing great weights; and in this cafe, the wheel may have cogs all round it inftead of handles, and a fmall lantern or trundle may be made to work in the cogs, and be turned by a winch ; which will make the power of the engine to exceed the power of the man who works it, as much as the number of revolutions of the winch exceed those of the axle D, when multiplied by the excels of the length of the winch above the length of the femidiameter of the axle. added to the femidiameter or half thickness of the rope K, by which the weight is drawn up.-Thus, fuppofe the diameter of the rope and axle taken together, to be 13 inches, and confequently, half their diameters to be 6 1 inches; fo that the weight W will hang at $6\frac{1}{2}$ inches perpendicular diftance from below the center of the axle. Now, let us fuppofe the wheel AB, which is fixt on the axle, to have 80 cogs, and to be turned by means of a winch 6 1 inches long, fixt on the axis of a trundle of 8 flaves or rounds, working in the cogs of the wheel -Here it is plain, that the winch and trundle would make 10 revolutions for one of the wheel AB, and its axis D, on which the rope K winds in raifing the weight W; and the winch being no longer than the fum of the femidiameters of the great axle and rope, the trundle could have no more power on the wheel, than a man could have by pulling it round by the edge, becaufe the winch would have no greater velocity than the edge of the wheel has, which we here fuppole to be ten times as great as the velocity of the rifing weight: fo that, in this cafe, the power gained would be as 10 to 1. But if the length of the winch be 13 inches, the power gained

gained will be as 20 to 1 : if 19 1 inches (which is long enough for any man to work by) the power gained would be as 30 to 1; that is, a man could raife 30 times as much by fuch an engine, as he could do by his natural ftrength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rifing weight; the abfolute force of any engine being in proportion of the velocity of the power to the velocity of the weight railed by it .- But then, just as much power or advantage as is gained by the engine, fo much time is loft in working it. In this fort of machines it is requifite to have a ratchet-wheel G on one end of the axle, with a catch H to fall into its teeth : which will at any time fupport the weight, and keep it from defcending, if the perfon who turns the handle fhould, through inadvertency or careleffnefs, quit his hold whilft the weight is raifing. And by this means, the danger is prevented which might otherwife happen by the running down of the weight when left at liberty.

3. The third mechanical power or engine con- The pulfifts either of one moveable pully, or a fystem of ley. pulleys; fome in a block or cafe which is fixed, and others in a block which is moveable, and rifes with the weight. For though a fingle pulley that only turns on its axis, and moves not out of its place, may ferve to change the direction of the power, yet it can give no mechanical advantage thereto; but is only as the beam of a balance, whole arms are of equal length and weight. Thus, if the equal weights W and P Fig. 6. hang by the cord B B upon the pulley A, whofe frame b is fixed to the beam H 1, they will counterpoife each other, just in the fame manner as if the cord were cut in the middle, and its two E 4 ends

ends hung upon the hooks fixt in the pulley at A and A, equally diffant from its center.

But if a weight W hangs at the lower end of the moveable block p of the pulley D, and the cord G F goes under that pulley, it is plain that the half \tilde{G} of the cord bears one half of the weight W, and the half F the other; for they bear the whole between them. Therefore, whatever holds the upper end of either rope, fuftains one half of the weight : and if the cord at F be drawn up fo as to raife the pulley D to C, the cord will then be extended to its whole length, all but that part which goes under the pulley : and confequently, the power that draws the cord will have moved twice as far as the pulley D with its weight W rifes; on which account, a power whole intenfity is equal to one half of the weight will be able to support it, because if the power moves (by means of a small addition) its velocity will be double the velocity of the weight; as may be feen by putting the cord over the fixt pulley C (which only changes the direction of the power, without giving any advantage to it) and hanging on the weight P. which is equal only to one half the weight W; in which cafe there will be an equilibrium, and a little addition to P will caufe it to defcend, and raife W through a space equal to one half of that through which P defcends .- Hence, the advantage gained will be always equal to twice the number of pulleys in the moveable or undermost block. So that, when the upper or fixt block u contains two pulleys, which only turn on their axes, and the lower or moveable block U contains two pulleys, which not only turn upon their axes, but alfo rife with the block and weight; the advantage gained by this is as 4 to the working

working power. Thus, if one end of the rope KMOQ be fixed to a hook at *I*, and the rope paffes over the pulleys N and R, and under the pulleys *L* and *P*, and has a weight *T*, of one pound, hung to its other end at *T*, this weight will balance and fupport a weight *W* of four pounds hanging by a hook at the moveable block *U*, allowing the faid block as a part of the weight. And if as much more power be added, as is fufficient to overcome the friction of the pulleys, the power will defeend with four times as much velocity as the weight rifes, and confequently through four times as much figure.

The two pulleys in the fixed block X, and the two in the moveable block Y, are in the fame cafe with those last mentioned; and those in the lower block give the fame advantage to the power.

As a fyftem of pulleys has no great weight, and lies in a fmall compafs, it is eafily carried about; and can be applied, in a great many cafes, for raifing weights, where other engines cannot. But they have a great deal of friction on three accounts: 1. Becaufe the diameters of their axes bear a very confiderable proportion to their own diameters; 2. Becaufe in working they are apt to rub againft one another, or againft the fides of the block; 3. Becaufe of the ftiffnefs of the rope that goes over and under them.

4. The fourth mechanical power is the *in*- The *in*clined plane and the advantage gained by it is clined as great as its length exceeds its perpendicular plane. height. Let AB be a plane parallel to the hori- Plat. VI. zon, and CD a plane inclined to it; and fuppofe Fig. 1. the whole length CD to be three times as great as the perpendicular height GfF: in this cafe, the cylinder E will be fupported upon the plane CD, C.D. and kept from rolling down upon it, by a power equal to a third part of the weight of the cylinder. Therefore, a weight may be rolled up this inclined plane with a third part of the power which would be fufficient to draw it up by the fide of an upright wall. If the plane was four times as long as high, a fourth part of the power would be fufficient; and fo on, in proportion. Or, if a weight was to be railed from a floor to the height G F, by means of the machine ABCD, (which would then act as a half wedge, where the refiftance gives way only on one fide) the machine and weight would be in equilibrio when the power applied at G F was to the weight to be raifed, as GF to GB; and if the power be increaled, fo as to overcome the friction of the machine against the floor and weight, the machine will be driven, and the weight raifed : and when the machine has moved its whole length upon the floor, the weight will be raifed to the whole height from G to F.

The force wherewith a rolling body defcends upon an inclined plane, is to the force of its abfolute gravity, by which it would defcend perpendicularly in a free space, as the height of the plane is to its length. For, suppose the plane A B to be parallel to the horizon, the cylinder C. will keep at reft upon any part of the plane where it is laid. If the plane be fo elevated, that its perpendicular height D is equal to half its length A B, the cylinder will roll down upon the plane with a force equal to half its weight; for it would require a power (acting in the direction of A B) equal to half its weight, to keep it from rolling. If the plane AB be elevated, fo as to be perpendicular to the horizon, the cylinder C will defcend with its whole force of gravity,

Fig. 2.

Fig. 3.

Fig. 4.

gravity, becaufe the plane contributes nothing to its fupport or hindrance; and therefore, it would require a power equal to its whole weight to keep it from defcending.

Let the cylinder C be made to turn upon Fig. 5. flender pivots in the frame D, in which there is a hook e, with a line G tied to it : let this line go over the fixed pulley H, and have its other end tied to the hook in the weight I. If the weight of the body I, be to the weight of the cylinder C, added to that of its frame D, as the perpendicular height of the plane L M is to its length AB, the weight will just support the cylinder upon the plane, and a fmall touch of a finger will either caufe it to afcend or defcend with equal eafe : then, if a little addition be made to the weight I, it will defcend, and draw the cylinder up the plane. In the time that the cylinder moves from A to B, it will rife through the whole height of the plane ML; and the weight will defcend from H to K, through a space equal to the whole length of the plane AB.

If the machine be made to move upon rollers or friction-wheels, and the cylinder be supported upon the plane CB by a line G parallel to the plane, a power fomewhat lefs than that which drew the cylinder up the plane will draw the plane under the cylinder, provided the pivots of the axes of the friction wheels be fmall, and the wheels themfelves be pretty large. For, let the machine A B C (equal in length and height to Fig. 6. A B M, Fig. 5.) move upon four wheels, two whereof appear at D and E, and the third under C, whillt the fourth is hid from fight by the horizontal board a. Let the cylinder F be laid upon the lower end of the inclined plane CB, and the line G be extended from the frame of the cylinder, about fix feet parallel to the plane

plane CB; and, in that direction, fixed to a hook in the wall; which will fupport the cylinder, and keep it from rolling off the plane. Let one end of the line H be tied to a hook at C in the machine, and the other end to a weight K, lomewhat lefs than that which drew the cylinder up the plane before. If this line be put over the fixed pulley I, the weight K will draw the machine along the horizontal plane L, and under the cylinder F: and when the machine has been drawn a little more than the whole length CA, the cylinder will be raifed to d, equal to the perpendicular height A B above the horizontal part at A. The reason why the machine must be drawn further than the whole length C A is, becaufe the weight F rifes perpendicular to C B.

To the inclined plane may be reduced all hatchets, chifels, and other edge-tools which are chamfered only on one fide. 5. The fifth mechanical power or machine is

The wedge.

Fig. 8.

the wedge, which may be confidered as two equally inclined planes D E F and C E F, joined together at their bafes e E F O; then D C is the whole thickness of the wedge at its back ABCD, where the power is applied : E F is the depth or heighth of the wedge : D F the length of one of its fides, equal to C F the length of the other fide; and O F is its fharp edge, which is entered into the wood intended to be fplit by the force of a hammer or mallet flriking perpendicularly on its back. Thus, ABb is a wedge driven into the cleft C D E of the wood FG.

Fig. 9.

When the wood does not cleave at any diftance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the refiftance of the wood acting against the two fides of the wedge when the power is to the refiftance, as half the thickness of

of the wedge at its back is to the length of either of its fides; because the refistance then acts perpendicular to the fides of the wedge. But, when the refiftance on each fide acts parallel to the back, the power that balances the refiftances on both fides will be as the length of the whole back of the wedge is to double its perpendicular height.

When the wood cleaves at any diftance before the wedge (as it generally does) the power impelling the wedge will not be to the refiftance of the wood, as the length of the back of the wedge is to the length of both its fides; but as half the length of the back is to the length of either fide of the cleft, effimated from the top or acting part of the wedge. For, if we fuppofe the wedge to be lengthened down from b to the bottom of the cleft at E, the fame proportion will hold; namely, that the power will be to the reliftance, as half the length of the back of the wedge is to the length of either of its fides : or, which amounts to the fame thing, as the whole length of the back is to the length of both the fides.

In order to prove what is here advanced concerning the wedge, let us suppose the wedge to be divided lengthwife into two equal parts; and then it will become two equal inclined planes; one of which, as a b c, may be made use of as a Fig. 7: half wedge for feparating the moulding c d from the wainfcot AB. It is evident, that when this half wedge has been driven its whole length ac between the wainfcot and moulding, its fide a c will be at ed; and the moulding will be feparated to f g from the wainfcot. Now, from what has been already proved of the inclined plane, it appears, that to have an equilibrium between the power impelling the half wedge, and the refiftance of the moulding, the former must be to the latter.

letter, as ab to ac; that is, as the thickness of the back which receives the ftroke is to the length of the fide against which the moulding acts. Therefore, fince the power upon the half wedge is to the refiftance against its fide, as the half back a b is to the whole fide a c, it is plain, that the power upon which the whole wedge (where the whole back is double the half back) must be to the refiftance against both its fides, as the thickness of the whole back is to the length of both the fides; fuppoling the wedge at the bottom of the cleft : or as the thickness of the whole back to the length of both fides of the cleft. when the wood fplits at any diftance before the wedge. For, when the wedge is driven quite into the wood, and the wood fplits at ever fo fmall a diftance before its edge, the top of the wedge then becomes the acting part, becaufe the wood does not touch it any where elfe. And fince the bottom of the cleft must be confidered as that part where the whole flickage or refiftance is accumulated, it is plain, from the nature of the lever, that the farther the power acts from the refiftance, the greater is the advantage.

Some writers have advanced, that the power of the wedge is to the refiftance to be overcome, as the thickness of the back of the wedge is to the length only of one of its fides; which feems very ftrange: for, if we suppose A B to be a ftrong inflexible bar of wood or iron fixt into the ground at C B, and D and E to be two blocks of marble lying on the ground on opposite fides of the bar; it is evident that the block D may be feparated from the bar to the diftance d, equal to a b, by driving the inclined plane or half wedge a b o down between them; and the block E may be feparated to an equal diftance on the other fide, in like manner, by the half wedge c d o. But

Fig. 10.

But the power impelling each half wedge will be to the refiftance of the block against its fide, as the thickness of that half wedge is to its perpendicular height, becaufe the block will be driven off perpendicular to the fide of the bar AB. Therefore the power to drive both the half wedges is to both the refiftances, as both the half backs is to the perpendicular height of each half wedge. And if the bar be taken away, the blocks put clofe together, and the two half wedges joined to make one; it will require as much force to drive it down between the blocks, as is equal to the fum of the feparate powers acting upon the half wedges when the bar was between them.

To confirm this by an experiment, let two Fig. 11. cylinders, as AB and CD, be drawn towards one another by lines running over fixed pulleys, and a weight of 40 ounces hanging at the lines belonging to each cylinder : and let a wedge of 40 ounces weight, having its back just as thick as either of its fides is long, be put between the cylinders, which will then act against each fide with a refiftance equal to 40 ounces, whilft its own weight endeavours to bring it down and feparate them. And here, the power of the wedge's gravity impelling it downward, will be to the refiftance of both the cylinders against the wedge, as the thickness of the wedge is to double its perpendicular height; for there will then be an equilibrium between the weight of the wedge and the refiftance of the cylinders against it, and it will remain at any height between them; requiring just as much power to push it upward as to pull it downward .- If another wedge of equal weight and depth with this, and only half as thick, be put between the cylinders, it will require twice as much weight to be hung at the ends

ends of the lines which draw them together, to keep the wedge from going down between them. That is, a wedge of 40 ounces, whofe back is only equal to half its perpendicular height, will require 80 ounces to each cylinder, to keep it in an equilibrium between them : and twice 80 is 160, equal to four times 40. So that the power will be always to the refiftance, as the thicknefs of the back of the wedge is to twice its perpendicular height, when the cylinders move off in a line at right angles to that perpendicular.

The beft way, though perhaps not the neateft, that I know of, for making a wedge with its appurtenances for fuch experiments, is as fol-Let KILM and LMNO be two flat lows. pieces of wood, each about fifteen inches long and three or four in breadth, joined together by a hinge at L M; and let P be a graduated arch of brafs, on which the faid pieces of wood may be opened to any angle not more than 60 degrees. and then fixt at the given angle by means of the two fcrews a and b. Then, IKNO will reprefent the back of the wedge, L M its fharp edge which enters the wood, and the outfides of the pieces KILM and LMNO the two fides of the wedge against which the wood acts in cleaving. By means of the faid arch, the wedge may be opened fo, as to adjust the thickness of its back in any proportion to the length of either of its fides, but not to exceed that length: and any weight as p may be hung to the wedge upon the hook M, which weight, together with the weight of the wedge itfelf, may be confidered as the impelling power; which is all the fame in the experiment, whether it be laid upon the back of the wedge, to push it down, or hung to its edge to pull it down.-Let AB and CD be two wooden cylinders, each about two inches thick, where they

Fig. 11.

67

they touch the outfides of the wedge; and let their ends be made like two round flat plates, to keep the wedge from flipping off edgewife from between them. Let a small cord with a loop on one end of it, go over a pivot in the end of each cylinder, and the cords S and T belonging to the cylinder AB goover the fixt pulleys W and X, and be fastened at their other ends to the bar w x, on which any weight as Z may be hung at pleafure. In like manner, let the cords 2 and R belonging to the cylinder CD goover the fixt pulleys V and Uto the bar vu, on which a weight Υ equal to Z may be hung. Thefe weights, by drawing the cylinders towards one another, may be confidered as the refiftance of the wood acting equally against opposite fides of the wedge; the cylinders themfelves being fufpended near, and parallel to each other, by their pivots in loops on the lines E, F, G, H; which lines may be fixed to hooks in the ceiling of the room. The longer thefe lines are, the better; and they fhould never be lefs than four feet each. The farther also the pulleys V,U and X,W are from the cylinders, the truer will the experiments be : and they may turn upon pins fixed into the wall.

In this machine, the weights Υ and Z, and the weight p, may be varied at pleature, fo as to be adjusted in proportion of double the wedge's perpendicular height to the thickness of its back : and when they are fo adjusted, the wedge will be in equilibrio with the resistance of the cylinders.

The wedge is a very great mechanical power, fince not only wood but even rocks can be fplit by it; which would be impossible to effect by the lever, wheel and axle, or pulley: for the force of the blow, or stroke, shakes the cohering parts, and thereby makes them separate the more easily,

F

6. The

Of the mechanical Powers. 6. The fixth and last mechanical power is the

ferew; which cannot properly be called a fimple

The Screw.

130

63

machine, becaufe it is never used without the application of a lever or winch to affift in turning it: and then it becomes a compound engine of a very great force either in preffing the parts of bodies clofer together, or in raifing great weights. It may be conceived to be made by cutting a piece of paper ABC (Fig. 12.) into Fig. 12, the form of an inclined plane or half wedge, and then wrapping it round a cylinder AB (Fig. 13). And here it is evident, that the winch E must turn the cylinder once round before the weight of reliftance D can be moved from one ipiral winding to another, as from d to c: therefore, as much as the circumference of a circle defcribed by the handle of the winch is greater than the interval or diftance between the fpirals, to much is the force of the fcrew. Thus, fuppoling the diftance between the fpirals to be half an inch, and the length of the winch to be twelve inches; the circle defcribed by the handle of the winch where the power acts will be 76 inches nearly, or about 152 half inches, and confequently 152 times as great as the diftance between the fpirals: and therefore a power at the handle, whose intensity is equal to no more than a fingle pound, will balance 152 pounds acting against the forew; and as much additional force, as is fufficient to overcome the friction, will raife the 152 pounds; and the velocity of the power will be to the velocity of the weight, as 152 to 1. Hence it appears, that the longer the winch is, and the nearer the fpirals are to one another, fo much the greater is the force of the fcrew.

> A machine for fhewing the force or power of the fcrew may be contrived in the following manner

manner. Let the wheel C have a fcrew a b on Fig. 14. its axis, working in the teeth of the wheel D, which fuppole to be 48 in number. It is plain, that for every time the wheel C and fcrew ab are turned round by the winch A, the wheel D will be moved one tooth by the fcrew; and therefore, in 48 revolutions of the winch, the wheel D will be turned once round. Then, if the circumference of a circle defcribed by the handle of the winch A be equal to the circumference of a groove e round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Confequently, if a line G (above number 48) goes round the groove e, and has a weight of 48 pounds hung to it below the pedeftal EF, a power equal to one pound at the handle will balance and fupport the weight .- To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then if a weight H of one pound be fulpended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line G; and a fmall addition to the weight Hwill caufe it to defcend, and fo raife up the other weight.

If the line G, instead of going round the groove e of the wheel D, goes round its axle I; the power of the machine will be as much increafed, as the circumference of the groove e exceeds the circumference of the axle : which, fuppoling it to be fix times, then one pound at H will balance 6 times 48, or 288 pounds hung to the line on the axle: and hence the power or advantage of this machine will be as 288 to 1. That is to fay, a man, who by his natural ftrength could lift an hundred weight, will be F 2

able

able to raife 288 hundred, or 145 ton weight by this engine.

But the following engine is ftill more powerful, on account of its having the addition of four pulleys : and in it we may look upon all the mechanical powers as combined together, Plate VII, even if we take in the balance. For, as the axis

D of the bar AB is in its middle at C, it is plain that if equal weights are fuspended upon any two A combi- pins equi-diftant from the axis C, they will counterpoife each other .- It becomes a lever by hanging a fmall weight P upon the pin n, and a weight as much heavier upon either of the pins b, c, d, e, or f, as is in proportion to the pins being fo much nearer the axis. The wheel and axle FG is evident; fo is the forew E which takes in the inclined plane, and with it the half wedge. Part of a cord goes round the axle, the reft under the lower pulleys K, m, over the upper pulleys L, n, and then it is tied to a hook at m in the lower or moveable block, on which the weight W hangs.

In this machine, if the wheel F has 30 teeth, it will be turned once round in thirty revolutions of the bar AB, which is fixt on the axis D of the forew E: if the length of the bar is equal to twice the diameter of the wheel, the pins a and n at the ends of the bar will move 60 times as fast as the teeth of the wheel do; and confequently, one ounce at P will balance 60 ounces hung upon a tooth at q in the horizontal diameter of the wheel. Then, if the diameter of the wheel F is ten times as great as the diameter of the axle G, the wheel will have 10 times the velocity of the axle; and therefore one ounce Pat the end of the lever AC will balance 10 times 60 or 600 ounces hung to the rope H which goes round

Fig. 1.

nation of all the mechanical powers.

round the axle. Laftly, if four pulleys be added, they will make the velocity of the lower block K, and weight W, four times lefs than the velocity of the axle : and this being the laft power in the machine, which is four times as great as that gained by the axle, it makes the whole power of the machine 4 times 600, or 2400. So that a man who could lift one hundred weight in his arms by his natural ftrength, would be able to raife 2400 times as much by this engine .- But it is here as in all other mechanical cafes; for the time loft is always as much as the power gained, becaufe the velocity with which the power moves will ever exceed the velocity with which the weight rifes, as much as the intenfity of the weight exceeds the intenfity of the power.

The friction of the fcrew itfelf is very confiderable; and there are few compound engines, but what, upon account of the friction of the parts against one another, will require a third part more of power to work them when loaded, than what is sufficient to constitute a balance between the weight and the power.

LECT. IV,

Of mills, cranes, wheel-carriages, and the engine for driving piles.

A S these engines are so universally useful, it would be needless to make any apology for describing them.

In a common breaft mill, where the fall of Plate VII. water may be about ten feet, AA is the great Fig. 2. wheel, which is generally about 17 or 18 feet in A com-F 3 diameter, mon mill.

diameter, reckoned from the outermost edge of any float board at *a* to that of its opposite float at *b*. To this wheel the water is conveyed through a channel, and by falling upon the wheel, turns it round.

On the axis B B of this wheel, and within the mill houfe, is a wheel D, about 8 or 9 feet diameter, having 61 cogs, which turn a trundle E containing ten upright flaves or rounds; and when these are the number of cogs and rounds, the trundle will make $6\frac{1}{10}$ revolutions for one revolution of the wheel.

The trundle is fixt upon a firong iron axis called the fpindle, the lower end of which turns in a brafs foot, fixt at F, in the horizontal beam STcalled the bridge-tree; and the upper part of the fpindle turns in a wooden bufh fixt into the nether millftone which lies upon beams in the floor TT. The top part of the fpindle above the bufh is fquare, and goes into a fquare hole in a firong iron crofs a b c d, (fee Fig. 3.) called the rynd; under which, and clofe to the bufh, is a round piece of thick leather upon the fpindle, which it turns round at the fame time as it does the rynd.

The rynd is let into grooves in the under furface of the running millftone G (Fig. 2.) and fo turns it round in the fame time that the trundle Eis turned round by the cog-wheel D. This millftone has a large hole quite through its middle, called the eye of the ftone, through which the middle part of the rynd and upper end of the fpindle may be feen; whilft the four ends of the rynd lie hid below the ftone in their grooves.

The end T of the bridge-tree TS (which fupports the upper millftone G upon the fpindle) is fixed into a hole in the wall; and the end S is let into a beam QR called the brayer, whose end Rremains

remains fixt in a mortife: and its other end \mathcal{Q} hangs by a ftrong iron rod P which goes through the floor \mathcal{TT} , and has a fcrew-nut on its top at O; by the turning of which nut, the end \mathcal{Q} of the brayer is raifed or deprefied at pleafure; and confequently the bridge-tree TS and upper millftone. By this means, the upper milliftone may be fet as clofe to the under one, or raifed as high from it, as the miller pleafes. The nearer the milliftones are to one another, the finer they grind the corn, and the more remote from one another, the coarfer.

The upper millftone G is inclosed in a round box H, which does not touch it any where; and is about an inch diftant from its edge all around. On the top of this box ftands a frame for holding the hopper k k, to which is hung the fhoe I by two lines fastened to the hind-part of it, fixed upon hooks in the hopper, and by one end of the crook-ftring K fastened to the fore-part of it at i; the other end being twifted round the pin L. As the pin is turned one way, the ftring draws up the fhoe closer to the hopper, and fo less the aperture between them; and as the pin is turned the other way, it lets down the fhoe, and enlarges the aperture.

If the fhoe be drawn up quite to the hopper, no corn can fall from the hopper into the mill; if it be let a little down, fome will fall: and the quantity will be more or lefs, according as the fhoe is more or lefs let down. For the hopper is open at bottom, and there is a hole in the bottom of the fhoe, not directly under the bottom of the hopper, but forwarder towards the end *i*, over the middle of the eye of the millftone.

There is a fquare hole in the top of the fpindle, Fig. 3. in which is put the feeder e: this feeder (as the

F 4

fpindle

fpindle turns round) jogs the floe three times in each revolution, and fo caufes the corn to run conftantly down from the hopper through the floe, into the eye of the millftone, where it falls upon the top of the rynd, and is, by the motion of the rynd, and the leather under it, thrown below the upper flone, and ground between it and the lower one. The violent motion of the flone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the center, as in a fpiral, in every revolution, until it be thrown quite out; and, being then ground, it falls through a fpout M, called the mill-eye, into the trough N.

When the mill is fed too faft, the corn bears up the flone, and is ground too coarfe; and befides, it clogs the mill fo as to make it go too flow. When the mill is too flowly fed, it goes too faft, and the flones by their attrition are apt to flrike fire againft one another. Both which inconveniences are avoided by turning the pin Lbackwards or forwards, which draws up or lets down the floe; and fo regulates the feeding as the miller fees convenient.

The heavier the running millfone is, and the greater the quantity of water that falls upon the wheel, fo much the fafter will the mill bear to be fed; and confequently fo much the more it will grind. And on the contrary, the lighter the ftone, and the lefs the quantity of water, fo much flower muft the feeding be. But when the ftone is confiderably wore, and become light, the mill muft be fed flowly at any rate; otherwife the ftone will be too much born up by the corn under it, which will make the meal coarfe.

The quantity of power required to turn a heavy millitone is but very little more than what

is fufficient to turn a light one: for as it is fupported upon the fpindle by the bridge-tree ST, and the end of the fpindle that turns in the brafs foot therein being but small, the odds arising from the weight is but very inconfiderable in its action against the power or force of the water. And besides, a heavy stone has the fame advantage as a heavy fly; namely, that it regulates the motion much better than a light one.

In order to cut and grind the corn, both the upper and under millftones have channels or furrows cut into them, proceeding obliquely from the center towards the circumference. And thefe furrows are cut perpendicularly on one fide and obliquely on the other into the ftone, which gives each furrow a fharp edge, and in the two ftones they come, as it were, against one another like the edges of a pair of fciffars : and fo cut the corn, to make it grind the eafier when it falls upon the places between the furrows. These are cut the fame way in both stones when they lie upon their backs, which makes them run crois ways to each other when the upper ftone is inverted by turning its furrowed furface towards that of the lower. For, if the furrows of both ftones lay the fame way, a great deal of the corn would be driven onward in the lower furrows. and fo come out from between the ftones without being either cut or bruifed.

When the furrows become blunt and fhallow by wearing, the running flone muft be taken up, and both flones new dreft with a chifel and hammer. And every time the flone is taken up, there muft be fome tallow put round the fpindle upon the bufh, which will foon be melted by the heat the fpindle acquires from its turning and rubbing againft the bufh, and fo will get in betwixt
76

betwixt them : otherwife the bufh would take fire in a very little time.

The bufh must embrace the fpindle quite clofe, to prevent any shake in the motion, which would make fome parts of the stores grate and fire against each other; whilst other parts of them would be too far afunder, and by that means spoil the meal in grinding.

Whenever the fpindle wears the bufh fo as to begin to shake in it, the stone must be taken up, and a chifel drove into feveral parts of the bufh ; and when it is taken out, wooden wedges muft be driven into the holes; by which means the bufh will be made to embrace the fpindle clofe all around it again. In doing this, great care must be taken to drive equal wedges into the built on opposite fides of the spindle; otherwise it will be thrown out of the perpendicular, and fo hinder the upper ftone from being fet parallel to the under one, which is abfolutely necessary for making good work. When any accident of this kind happens, the perpendicular polition of the fpindle muft be reftored by adjufting the bridgetree ST by proper wedges put between it and the brayer 2 R.

It often happens, that the rynd is a little wrenched in laying down the upper ftone upon it; or is made to fink a little lower upon one fide of the fpindle than on the other; and this will caufe one edge of the upper ftone to drag all around upon the other, whilft the oppofite edge will not touch. But this is eafily fet to rights, by raifing the ftone a little with a lever, and putting bits of paper, cards or thin chips, between the rynd and the ftone.

The diameter of the upper flone is generally about fix feet, the lower flone about an inch more :

more: and the upper from when new contains about $22\frac{1}{2}$ cubc feet, which weighs fomewhat more than 19000 pounds. A from of this diameter ought never to go more than 60 times round in a minute; for if it turns fafter, it will heat the meal.

The grinding furface of the under ftone is a little convex from the edge to the center, and that of the upper ftone a little more concave: fo that they are fartheft from one another in the middle, and come gradually nearer towards the edges. By this means, the corn at its first entrance between the ftones is only bruifed; but as it goes farther on towards the circumference or edge, it is cut fmaller and fmaller; and at laft finely ground juft before it comes out from between them.

The water-wheel muft not be too large, for if it be, its motion will be too flow; nor too little, for then it will want power. And for a mill to be in perfection, the floats of the wheel ought to move with a third part of the velocity of the water, and the flone to turn round once in a fecond of time.

In order to conftruct a mill in this perfect manner, observe the following rules:

1. Meafure the perpendicular height of the fall of water, in feet, above that part of the wheel on which the water begins to act; and call that, the height of the fall.

2. Multiply this conftant number 64.2882 by the height of the fall in feet, and the fquare root of the product shall be the velocity of the water at the bottom of the fall, or the number of feet that the water there moves *per* fecond.

3. Divide the velocity of the water by 3, and the quotient thall be the velocity of the floatboards of the wheel; or the number of feet they I muft

must each go through in a fecond, when the water acts upon them fo, as to have the greatest power to turn the mill.

4. Divide the circumference of the wheel in feet by the velocity of its floats in feet *per* fecond, and the quotient fhall be the number of feconds in which the wheel turns round.

5. By this laft number of feconds divide 60; and the quotient fhall be the number of turns of the wheel in a minute.

6. Divide 60 (the number of revolutions the millftone ought to have in a minute) by the number of turns of the wheel in a minute, and the quotient shall be the number of turns the mill-ftone ought to have for one turn of the wheel.

7. Then, as the number of turns of the wheel in a minute is to the number of turns of the millftone in a minute, fo must the number of flaves in the trundle be to the number of cogs in the wheel, in the nearest whole numbers that can be found.

By these rules I have calculated the following table to a water wheel 18 feet diameter, which I apprehend may be a good fize in general.

To conftruct a mill by this table, find the height of the fall of water in the firft column, and against that height, in the fixth column, you have the number of cogs in the wheel, and staves in the trundle, for causing the millstone to make about 60 revolutions in a minute, as near as possible, when the wheel goes with a third part of the velocity of the water. And it appears by the 7th column, that the number of cogs in the wheel, and flaves in the trundle, are fo near the truth for the required purpose, that the least number of revolutions of the millstone in a minute is between 59 and 60, and the greaest number never amounts to 61.

Such

Such a mill as this, with a fall of water about $7\frac{1}{2}$ feet, will require about 32 hogfheads every minute to turn the wheel with a third part of the velocity with which the water falls; and to overcome the refiftance arifing from the friction of the geers and attrition of the ftones in grinding the corn.

The greater fall the water has, the lefs quantity of it will ferve to turn the mill. The water is kept up in the mill-dam, and let out by a fluice called the penftock, when the mill is to go. When the penftock is drawn up by means of a lever, it opens a paffage through which the water flows to the wheel: and when the mill is to be ftopt, the penftock is let down, which ftops the water from falling upon the wheel.

A lefs quantity of water will turn an overfhotmill (where the wheel has buckets inftead of float-boards) than a breaft-mill where the fall of the water feldom exceeds half the height Ab of the wheel. So that, where there is but a fmall quantity of water, and a fall great enough for the wheel to lie under it, the bucket (or overfhot) wheel is always used. But where there is a large body of water, with a little fall, the breaft or float. board wheel must take place. Where the water runs only upon a little declivity, it can act but flowly upon the under part of the wheel at b_{i} in which cafe, the motion of the wheel will be very flow : and therefore, the floats ought to be very long, though not high, that a large body of water may act upon them; fo that what is wanting in velocity may be made up in power: and then the cog-wheel may have a greater number of cogs in proportion to the rounds in the trundle, in order to give the millftone a fufficient degree of velocity.

They who have read what is faid in the firft lecture, concerning the acceleration of bodies falling

falling freely by the power of gravity acting conftantly and uniformly upon them, may perhaps afk, Why fhould the motion of the wheel beequable, and not accelerated, feeing the water acts conftantly and uniformly upon it ? The plain answer is, That the velocity of the wheel can never be fo great as the velocity of the water that turns it; for, if it should become fo great, the power of the water would be quite loft upon the wheel, and then there would be no proper force to overcome the friction of the geers and attrition of the ftones. Therefore, the velocity with which the wheel begins to move, will increafe no longer than till its momentum or force is balanced by the refiftance of the working parts of the mill; and then the wheel will go on with an equable motion.

[If the cog wheel D be made about 18 inches A banddiameter, with 30 cogs, the trundle as fmall in mill. proportion, with 10 ftaves, and the millftones be each about two feet in diameter, and the whole work be put into a ftrong frame of wood, as reprefented in the figure, the engine will be a handmill for grinding corn or malt in private families. And then, it may be turned by a winch inftead of the wheel AA: the millftone making three revolutions for every one of the winch. If a heavy fly be put upon the axle B, near the winch, it will help to regulate the motion.]

If the cogs of the wheel and rounds of the trundle could be put in as exactly as the teeth are cut in the wheels and pinions of a clock, then the trundle might divide the wheel exactly: that is to fay, the trundle might make a given number of revolutions for one of the wheel, without a fraction. But as any exact number is not neceffary in mill-work, and the cogs and rounds cannot be fet in fo truly as to make all the

Of Horfe-Mills and Wind-Mills.

the intervals between them equal; a fkilful mill-wright will always give the wheel what he calls a *bunting cog*; that is, one more than what will anfwer to an exact division of the wheel by the trundle. And then, as every cog comes to the trundle, it will take the next ftaff or round behind the one which it took in the former revolution: and by that means, will wear all the parts of the cogs and rounds which work upon one another equally, and to equal diffances from one another in a little time; and fo make a true uniform motion throughout the whole work. Thus, in the above water-mill, the trundle has 10 ftaves, and the wheel 61 cogs.

Sometimes, where there is a fufficient quantity of water, the cog-wheel A A turns a large trundle BB, on whofe axis C is fixed the horizontal wheel D, with cogs all around its edge, turning two trundles E and F at the fame time; whole axes or fpindles G and H turn two millftones I and K, upon the fixed ftones L and M. And when there is not work for them both. either may be made to lie quiet, by taking out one of the flaves of its trundle, and turning the vacant place towards the cog wheel D. And there may be a wheel fixt on the upper end of the great upright axle C for turning a couple of boulting-mills; and other work for drawing up the lacks, fanning and cleaning the corn, fharpening of tools, &c.

A Horjemill.

Fig. 4.

If, inflead of the cog-wheel AA and trundle BB, horizontal levers be fixed into the axle C, below the wheel D; then, horfes may be put to thefe levers for turning the mill: which is often done where water cannot be had for that purpofe.

A windmill. The working parts of a wind-mill differ very little from those of a water-mill; only the former is

a man and the second PLATE .VIII. Fig. 1. 1 II ig. Fig. 2. T CA A (11) (11) (2) B Fig. 6.4 G В Fig.3 H J. Mynde Jo. J. Forguson delin.

Of Wind-Mills.

is turned by the action of the wind upon four fails, every one of which ought (as is generally believed) to make an angle of $54\frac{2}{3}$ degrees with a plane perpendicular to the axis on which the arms are fixt for carrying them. It being demonftrable, that when the fails are fet to fuch an angle, and the axis turned end-ways toward the wind, the wind has the greatest power upon the fails. But this angle answers only to the case of a vane or fail just beginning to move*: for, when the vane has a certain degree of motion, it yields to the wind; and then that angle mult be increased to give the wind its full effect.

Again, the increase of this angle should be different, according to the different velocities from the axis to the extremity of the vane. At the axis it should be $54\frac{\pi}{3}$ degrees, and thence continually decrease, giving the vane a twist, and fo causing all the ribs of the vane to lie in different planes.

Laftly, Thefe ribs ought to decreafe in length from the axis to the extremity, giving the vane a curvilineal form,; fo that no part of the force of any one rib be fpent upon the reft, but all move on independent of each other. All this is required to give the fails of a wind-mill their true form : and we fee both the twift and the diminution of the ribs exemplified in the wings of birds.

It is almost incredible to think with what velocity the tips of the fails move when acted upon by a moderate gale of wind. I have feveral times counted the number of revolutions made by the fails in ten or fifteen minutes; and from the length of the arms from tip to tip, have computed, that if a hoop of that diameter was to run upon the ground with the fame velo-

G

* See MACLAURIN's Fluxions, near the end.

city

city that it would move if put upon the fail-arms, it would go upwards of 30 miles in an hour.

As the ends of the fails nearest the axis cannot move with the fame velocity that the tips or fartheft ends do, although the wind acts equally ftrong upon them; perhaps a better position than that of ftretching them along the arms directly from the center of motion, might be to have them fet perpendicularly across the farther ends of the arms, and there adjusted lengthwife to the proper angle. For, in that cafe, both ends of the fails would move with the fame velocity; and being farther from the center of motion, they would have fo much the more power : and then, there would be no occasion for having them to large as they are generally made ; which would render them lighter, and confequently, there would be fo much the lefs friction on the thick neck of the axle where it turns in the wall.

A crane.

Fig. 1.

A crane is an engine by which great weights are raifed to certain heights, or let down to certain depths. It confifts of wheels, axles, pul-Plate VIII. leys, ropes, and a gib or gibber. When the rope H is hooked to the weight K, a man turns the winch A, on the axis whereof is the trundle B, which turns the wheel C, on whole axis D is the trundle E, which turns the wheel F with its upright axis G, on which the great rope HHwinds as the wheel turns; and going over a pulley I at the end of the arm d of the gib c c de, it draws up the heavy weight K; which, being railed to a proper height, as from a ship to the quay, is then brought over the quay by pulling the wheel Z round by the handles z, z, which turns the gib by means of the half wheel b fixt on the gib-post cc, and the ftrong pinion a fixt on the axis of the wheel Z. This wheel gives the man that turns it an abfolute command over the 3

85

the gib, fo as to prevent it from taking any unlucky fwing, fuch as often happens when it is only guided by a rope tied to its arm d; and people are frequently hurt, fometimes killed, by fuch accidents.

The great rope goes between two upright rollers i and k, which turn upon gudgeons in the fixed beams f and g; and as the gib is turned towards either fide, the rope bends upon the roller next that fide. Were it not for these rollers, the gib would be quite unmanageable; for the moment it were turned ever fo little towards any fide, the weight K would begin to defcend, becaufe the rope would be fhortened between the pulley I and axis G; and fo the gib would be pulled violently to that fide, and either be broke to pieces, or break every thing that came in its way. These rollers must be placed fo, that the fides of them, round which the rope bends, may keep the middle of the bended part directly even with the center of the hole in which the upper gudgeon of the gib turns in the beam f. The truer these rollers are placed, the eafier the gib is managed, and the lefs apt to fwing either way by the force of the weight K.

A ratchet-wheel 2 is fixt upon the axis D, near the trundle E; and into this wheel the catch or click R falls. This hinders the machinery from runing back by the weight of the burden K, if the man who raifes it fhould happen to be carelefs, and fo leave off working at the winch A fooner than he ought to do.

When the weight K is raifed to its proper height from the thip, and brought over the quay by turning the gib about, it is let down gently upon the quay, or into a cart ftanding thereon, in the following manner : A man takes hold of the rope tt (which goes over the pulley G 2

w. and

v, and is tied to a hook at S in the catch R) and fo difengages the catch from the ratchet-wheel Q; and then, the man at the winch A turns it backward, and lets down the weight K. But if the weight pulls too hard againft this man, another lays hold of the flick V, and by pulling it downward, draws the gripe U close to the wheel Y, which, by rubbing hard againft the gripe, hinders the too quick defcent of the weight; and not only fo, but even flops it at any time, if required. By this means, heavy goods may be either raifed or let down at pleafure without any danger of hurting the men who work the engine.

When part of the goods are craned up, and the rope is to be let down for more, the catch R is first difengaged from the ratchet-wheel 2, by pulling the cord t; then the handle q is turned half round backward, which, by the crank n n in the piece o, pulls down the frame b between the guides m and m (in which it flides in a groove) and fo difengages the trundle B from the wheel C: and then, the heavy book β at the end of the rope H defcends by its own weight, and turns back the great wheel F with its trundle E, and the wheel C; and this laft wheel acts like a fly against the wheel F and hook B; and fo hinders it from going down too quick; whilft the weight X keeps up the gripe U from rubbing against the wheel Y, by means of a cord going from the weight, over the pulley w to the hook W in the gripe; fo that the gripe never touches the wheel, unlefs it be pulled down by the handle V.

When the crane is to be fet at work again, for drawing up another burden, the handle q is turned half round forwards; which, by the crank nn, raifes up the frame b, and caufes the g

trundle B to lay hold of the wheel C; and then, by turning the winch \mathcal{A} , the burden of goods K is drawn up as before.

The crank n n turns pretty fliff in the mortife near o, and flops against the farther end of it when it has got just a little beyond the perpendicular; fo that it can never come back of it, felf: and therefore, the trundle B can never come away from the wheel C, until the handle q be turned half round, backwards.

The great rope runs upon rollers in the lever L M, which keeps it from bending between the axle at G and the pulley I. This lever turns upon the axis N by means of the weight O, which is just fufficient to keep its end L up to the rope; fo that, as the great axle turns, and the rope coils round it, the lever rifes with the rope, and prevents the coilings from going over one another.

The power of this crane may be effimated thus: fuppofe the trundle B to have 13 flaves or rounds, and the wheel C to have 78 fpur cogs; the trundle E to have 14 flaves, and the wheel F 56 cogs. Then, by multiplying the flaves of the trundles, 13 and 14, into one another, their product will be 182; and by multiplying the cogs of the wheels, 78 and 56, into one another, their product will be 4368, and dividing 4368 by 182, the quotient will be 24; which fhews that the winch A makes 24 turns for one turn of the wheel F and its axle G on which the great rope or chain HIHwinds. So that, if the length or radius of the winch A were only equal to half the diameter. of the great axle G, added to half the thickness of the rope H, the power of the crane would be as 24 to 1: but the radius of the winch being double the above length, it doubles the faid power, and to makes it as 48 to 1 : in which cafe, a man may raile 48 times as much weight G 2 by

by this engine as he could do by his natural ftrength without it, making proper allowance for the friction of the working parts.—Two men may work at once, by having another winch on the opposite end of the axis of the trundle under B; and this will make the power double.

If this power be thought greater than what may be generally wanted, the wheels may be made with fewer cogs in proportion to the flaves in the trundles; and fo the power may be of whatever degree is judged to be requifite. But if the weight be fo great as will require yet more power to raife it (fuppofe a double quantity) then the rope H may be put under a moveable pulley, as δ , and the end of it tied to a hook in the gib at ε ; which will give a double power to the machine, and fo raife a double weight hooked to the block of the moveable pulley.

When only fmall burthens are to be raifed, this may be quickly done by men pufhing the axle G round by the long fpokes y, y, y, y; having firft difengaged the trundle B from the wheel C: and then, this wheel will only act as a fly upon the wheel F; and the catch R will prevent its running back, if the men fhould inadvertently leave off pufhing before the burthen be unhooked from β .

Laftly, When very heavy burthens are to be raifed, which might endanger the breaking of the cogs in the wheel F; their force against thefe cogs may be much abated by men pulling round the long spokes y, y, y, y, whilst the man at Aturns the winch.

I have only fhewn the working parts of this crane, without the whole of the beams which fupport them; knowing that these are eafily fupposed,

fuppoled, and that if they had been drawn, they would have hid a great deal of the working parts from fight, and also confused the figure.

Another very good crane is made in the fol- Another lowing manner. A A is a great wheel turned crane. by men walking within it at H. On the part Fig. 2. C, of its axle B C, the great rope D is wound as the wheel turns; and this rope draws up goods in the fame way as the rope H H does in the above-mentioned crane, the gib-work here being fuppofed to be of the fame fort. But thefe cranes are very dangerous to the men in the wheel; for, if any of the men should chance to fall, the burthen will make the wheel run back and throw them all about within it; which often breaks their limbs, and fometimes kills them. The late ingenious Mr. Padmore of Briftol, (whole contrivance the forementioned crane is, fo far as I can remember its conftruction, after feeing it once about twelve years ago *,) observing this dangerous construction, contrived a method for remedying it, by putting cogs all around the outfide of the wheel, and applying a trundle E to turn it; which increases the power as much as the number of cogs in the wheel is greater than the number of staves in the trundle: and by putting a ratchet-wheel F on the axis of the trundle, (as in the abovementioned crane) with a catch to fall into it, the great wheel is ftopt from running back by the force of the weight, even if all the men in

* Since the first edition of this book was printed, I have feen the fame crane again; and do find, that though the working parts are much the fame as above defcribed, yet the method of raifing or lowering the trundle B, and the catch R, are better contrived than I had defcribed them.

it

80

it should leave off walking. And by one man working at the winch I, or two men at the oppofite winches when needful, the men in the wheel are much affifted, and much greater weights are raifed, than could be by men only within the wheel. Mr. Padmore put alfo a gripe-wheel G upon the axis of the trundle, which being pinched in the fame manner as defcribed in the former crane, heavy burthens may be let down without the least danger. And before this contrivance, the lowering of goods was always attended with the utmoft danger to the men in the wheel; as every one muft be fenfible of, who has feen fuch engines at work.

And it is furprifing that the mafters of wharfs and cranes fhould be fo regardlefs of the limbs, or even lives of their workmen, that excepting the late Sir James Creed of Greenwich, and fome gentlemen at Briftol, there is fcarce an inftance of any who has used this fafe contrivance.

Wheel-

The structure of wheel-carriages is generally carriages. fo well known, that it would be needless to defcribe them. And therefore, we shall only point out fome inconveniencies attending the common method of placing the wheels, and loading the waggons.

In coaches, and all other four-wheeled carriages, the fore-wheels are made of a lefs fize than the hind ones, both on account of turning fhort, and to avoid cutting the braces : otherwife, the carriage would go much eafier if the fore-wheels were as high as the hind ones, and the higher the better, becaufe they would fink to lefs depths in little hollowings in the roads, and be the more eafily drawn out of them.

them. But carriers and coachmen give another reafon for making the fore-wheels much lower than the hind-wheels; namely, that when they are fo, the hind-wheels help to push on the fore ones : which is too unphilosophical and abfurd to deferve a refutation, and yet for their fatisfaction we shall shew by experiment that it has no existence but in their own imaginations.

It is plain that the fmall wheels must turn as much oftener round than the great ones, as their circumferences are lefs. And therefore, when the carriage is loaded equally heavy on both axles, the fore-axle must fustain as much more friction, and confequently wear out as much fooner, than the hind-axle, as the forewheels are lefs than the hind-ones. But the great misfortune is, that all the carriers to a man do obstinately perfist, against the clearest reason and demonstration, in putting the heavier part of the load upon the fore-axle of the waggon; which not only makes the friction greateft where it ought to be least, but also preffeth the fore-wheels deeper into the ground than the hind-wheels, notwithstanding the fore-wheels, being lefs than the hind ones, are with fo much the greater difficulty drawn out of a hole or over an obstacle, even supposing the weights on their axles were equal. For the difficulty, with equal weights, will be as the depth of the hole Fig. 3. or height of the obstacle is to the semidiameter of the wheel. Thus, if we suppose the small wheel D of the waggon AB to fall into a hole of the depth EF, which is equal to the femidiameter of the wheel, and the waggon to be drawn horizontally along; it is evident, that the point E of the fmall wheel will be drawn directly against the top of the hole; and therefore,

91

92

fore, all the power of horfes and men will not be able to draw it out, unlefs the ground gives way before it. Whereas, if the hind-wheel G falls into fuch a hole, it finks not near fo deep in proportion to its femidiameter; and therefore, the point G of the large wheel will not be drawn directly, but obliquely, against the top of the hole; and fo will be eafily got out of it. Add to this, that as a fmall wheel will often fink to the bottom of a hole, in which a great wheel will go but a very little way, the fmall wheels ought in all reason to be loaded with lefs weight than the great ones : and then the heavier part of the load would be lefs jolted upward and downward, and the horfes tired fo much the lefs, as their draught raifed the load to lefs heights.

It is true, that when the waggon-road is much up-hill, there may be danger in loading the hind part much heavier than the fore part; for then the weight would overhang the hindaxle, efpecially if the load be high, and endanger tilting up the fore-wheels from the ground. In this cafe, the fafeft way would be to load it equally heavy on both axles; and then, as much more of the weight would be thrown upon the hind-axle than upon the fore one, as the ground riles from a level below the carriage. But as this feldom happens, and when it does, a fmall temporary weight laid upon the pole between the horfes would overbalance the danger; and this weight might be thrown into the waggon when it comes to level ground ; it is ftrange that an advantage fo plain and obvious as would arife from loading the hind-wheels heaviest, should not be laid hold of, by complying with this method.

To confirm thefe reafonings by experiment, let a fmall model of a waggon be made, with its fore-wheels 21 inches in diameter, and its hind-wheels 4; the whole model weighing about 20 ounces. Let this little carriage be loaded any how with weights, and have a fmall cord tied to each of its ends, equally high from the ground it refts upon; and let it be drawn along a horizontal board, first by a weight in a fcale hung to the cord at the fore-part; the cord going over a pulley at the end of the board to facilitate the draught, and the weight just fufficient to draw it along. Then, turn the carriage, and hang the fcale and weight to the hind cord, and it will be found to move along with the fame velocity as at first : which shews, that the power required to draw the carriage is all the fame, whether the great or fmall wheels are foremost; and therefore the great wheels do not help in the leaft to pulh on the fmall wheels in the road.

Hang the fcale to the fore-cord, and place the fore-wheels (which are the fmall ones) in two holes, cut three eight parts of an inch deep into the board; then put a weight of 32 ounces into the carriage, over the fore-axle, and an equal weight over the hind one: this done, put 44 ounces into the fcale, which will be just fufficient to draw out the fore-wheels : but if this weight be taken out of the fcale, and one of 16 ounces put into its place, if the hindwheels are placed in the holes, the 16 ounce weight will draw them out; which is little more than a third part of what was necessary to draw out the fore-wheels. This fhews, that the larger the wheels are, the lefs power will draw the carriage, efpecially on rough ground.

Put

93

Put 64 ounces over the axle of the hindwheels, and 32 over the axle of the fore-ones, in the carriage; and place the fore wheels in the holes: then, put 38 ounces into the fcale, which will just draw out the fore-wheels; and when the hind ones come to the hole, they will find but very little refistance, because they fink but a little way into it.

But fhift the weights in the carriage, by putting the 32 ounces upon the hind-axle, and the 64 ounces upon the fore one; and place the fore-wheels in the holes : then, if 76 ounces be put into the fcale, it will be found no more than fufficient to draw out thefe wheels; which is double the power required to draw them out, when the lighter part of the load was put upon them : which is a plain demonstration of the abfurdity of putting the heavieft part of the load in the fore-part of the waggon.

Every one knows what an out-cry was made by the generality, if not the whole body, of the carriers, against the broad-wheel act; and how hard it was to perfuade them to comply with it, even though the government allowed them to draw with more horfes, and carry greater loads, than ufual. Their principal objection was, that as a broad wheel must touch the ground in a great many more points than a narrow wheel, the friction must of course be just fo much the greater ; and confequently, there must be fo many more horfes than ufual, to draw the waggon. I believe that the majority of people were of the fame opinion, not confidering, that if the whole weight of the waggon and load in it bears upon a great many points, each fuftains a proportionably lefs degree of weight and friction, than when it bears only upon a few points; to that what

what is wanting in one, is made up in the other; and therefore will be just equal under equal degrees of weight, as may be shewn by the following plain and easy experiment.

Let one end of a piece of packthread be fastened to a brick, and the other end to a common fcale for holding weights : then, having laid the brick edgewife on a table, and let the icale hang under the edge of the table, put as much weight into the fcale as will just draw the brick along the table. Then taking back the brick to its former place, lay it flat on the table, and leave it to be acted upon by the fame weight in the fcale as before, which will draw it along with the fame eafe as when it lay upon its edge. In the former cafe, the brick may be confidered as a narrow wheel on the ground; and in the latter as a broad wheel. And fince the brick is drawn along with equal eafe, whether its broad fide or narrow edge touches the table, it fhews that a broad wheel might be drawn along the ground with the fame eafe as a narrow one (fuppoling them equally heavy) even though they fhould drag, and not roll, as they go along.

As narrow wheels are always finking into the ground, efpecially when the heavieft part of the load lies upon them, they muft be confidered as going conftantly up hill, even on level ground. And their fides muft fuftain a great deal of friction by rubbing againft the ruts made by them. But both thefe inconveniencies are avoided by broad wheels; which, inftead of cutting and ploughing up the roads, roll them fmooth, and harden them; as experience teffifies in places where they have been ufed, efpecially either on wettifh or fandy ground: though after all it muft be confeffed, that they will not do in ftiff clayey crofs roads;

96

roads; becaufe they would foon gather up as much clay as would be almost equal to the weight of an ordinary load.

If the wheels were always to go upon fmooth and level ground, the beft way would be to make the spokes perpendicular to the naves; that is, to ftand at right angles to the axles; because they would then bear the weight of the load perpendicularly, which is the ftrongeft way for But because the ground is generally unwood. even, one wheel often falls into a cavity or rut when the other does not; and then it bears much more of the weight than the other does; in which cafe, concave or difhing wheels are beft, becaule when one falls into a rut, and the other keeps upon high ground, the spokes become perpendicular in the rut, and therefore have the greateft ftrength when the obliquity of the load throws most of its weight upon them; whilst those on the high ground have less weight to bear, and therefore need not be at their full ftrength. So that the ufual way of making the wheels concave is by much the beft.

The axles of the wheels ought to be perfectly ftraight, that the rim of the wheels may be parallel to each other; for then they will move eafieft, becaufe they will be at liberty to go on ftraight forwards. But in the ufual way of practice, the axles are bent downward at their ends; which brings the fides of the wheels next the ground nearer to one another than their oppofite or higher fides are: and this not only makes the wheels to drag fidewife as they go along, and gives the load as much greater power of crufhing them than when they are parallel to each other, but alfo endangers the over-turning of the carriage when any wheel falls into a hole or rut; or when

when the carriage goes in a road which has one fide lower than the other, as along the fide of a hill. Thus (in the hind view of a waggon or cart) let AE and BF be the great wheels parallel to each other, on their straight axle K, and Fig. 4. HC I the carriage loaded with heavy goods from C to G. Then, as the carriage goes on in the oblique road A a B, the center of gravity of the whole machine and load will be at C*; and the * See line of direction C d D falling within the wheel page 13. BF, the carriage will not overfet. But if the wheels be inclined to each other on the ground, Fig. 5. as AE and BF are, and the machine be loaded as before, from C to G, the line of direction CdD falls without the wheel B F, and the whole machine tumbles over. When it is loaded with heavy goods (fuch as lead or iron) which lie low, Fig. 4. it may travel fafely upon an oblique road fo long as the center of gravity is at C, and the line of direction C d falls within the wheels; but if it be loaded high with lighter goods (fuch as woolpacks) from C to L, the center of gravity is raifed Fig. 6. from C to K, which throws the line of direction K k without the loweft edge of the wheel B F, and then the load overfets the waggon.

If there be fome advantage from fmall forewheels, on account of the carriage turning more cafily and fhort than it can be made to do when they are large; there is at leaft as great a difadvantage attending them, which is, that as their axle is below the level of the horfes breafts, the horfes not only have the loaded carriage to draw along, but also part of its weight to bear; which tires them fooner, and makes them grow much stiffer in their hams, than they would be if they drew on a level with the foreaxle. And for this reafon, we find coach horfes foon

97

Of the Pile-Engine.

foon become unfit for riding. So that on all accounts it is plain, that the fore-wheels of all carriages ought to be fo high, as to have their axles even with the breaft of the horfes; which would not only give the horfes a fair draught, but likewife keep them longer fit for drawing the carriage.

Plate IX. Fig. 1, 2.

We fhall conclude this lecture with a defeription of Mr. *Vauloue*'s curious engine, which was made use of for driving the piles of Westminsterbridge: and the reader may cast his eyes upon the first and second figures of the plate, in which the fame letters of reference are annexed to the fame parts, in order to explain those in the fecond, which are either partly or wholly hid in the first.

The pile.

A is the great upright fhaft or axle, on which are the great wheel B and drum C, turned by horfes joined to the bars S. S. The wheel B turns the trundle X, on the top of whofe axis is the fly O, which ferves to regulate the motion, and alfo to act against the horses, and keep them from falling when the heavy ram Q is difcharged to drive the pile P down into the mud in the bottom of the river. The drum C is loofe upon the fhaft A, but is locked to the wheel B by the bolt Υ . On this drum the great rope HH is wound; one end of the rope being fixed to the drum, and the other to the follower G, to which it is conveyed over the pulleys I and K. In the follower G is contained the tongs F (fee Fig. 2.) that takes hold of the ram 2 by the ftaple R for drawing it up. D is a fpiral or fuly fixt to the drum, on which is wound the finall rope Tthat goes over the pulley U, under the pulley V, and is fastened to the top of the frame at 7. To the pulley block V is hung the counterpoife W, which

Of the Pile-Engine.

which hinders the follower from accelerating as it goes down to take hold of the ram : for, as the follower tends to acquire velocity in its defcent, the line T winds downwards upon the fufy, on a larger and larger radius, by which means the counterpoife W acts ftronger and ftronger against it; and fo allows it to come down with only a moderate and uniform velocity. The bolt \mathcal{X} locks the drum to the great wheel, being pushed upward by the small lever 2, which goes through a mortife in the fhaft A, turns upon a pin in the bar 3 fixt to the great wheel B, and has a weight 4, which always tends to push up the bolt I through the wheel into the drum. L is the great lever turning on the axis m, and refting upon the forcing bar 5, 5, which goes down through a hollow in the fhaft A, and bears up the little lever 2.

By the horfes going round, the great rope His wound about the drum C, and the ram Q is drawn up by the tongs F in the follower G, until the tongs comes between the inclined planes E; which, by fhutting the tongs at the top, opens it at the foot, and difcharges the ram, which falls down between the guides b b upon the pile P; and drives it by a few ftrokes as far into the mud as it can go; after which, the top part is fawed off close to the mud, by an engine for that pur-Immediately after the ram is difcharged, pofe. the piece 6 upon the follower G takes hold of the ropes a, a, which raife the end of the lever L, and cause its end N to descend and press down the forcing bar 5 upon the little lever 2, which by pulling down the bolt Υ , unlocks the drum Gfrom the great wheel B; and then, the follower, being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs flip H over

Of the Pile-Engine.

over the ftaple R, and the weight of their heads caufes them to fall outward, and fhuts upon it. Then the weight 4 puffies up the bolt T into the drum, which locks it to the great wheel, and fo the ram is drawn up as before.

As the follower comes down, it caufes the drum to turn backward, and unwinds the rope from it, whilft the horfes, great wheel, trundle and fly, go on with an uninterrupted motion : and as the drum is turning backward, the counterpoife W is drawn up, and its rope T wound upon the fpiral fuly D.

There are feveral holes in the under fide of the drum, and the bolt \mathcal{X} always takes the first one that it finds when the drum stops by the falling of the follower upon the ram; until which stoppage, the bolt has not time to flip into any of the holes.

This engine was placed upon a barge on the water, and fo was eafily conveyed to any place defired.—I never had the good fortune to fee it, but drew this figure from a model which I made from a print of it; being not quite fatisfied with the view which the print gives. I have been told that the ram was a ton weight, and that the guides b b, between which it was drawn up and let fall down, were 30 feet high. I fuppofe the great wheel may have had 100 cogs, and the trundle 10 flaves or rounds; fo that the fly would make 10 revolutions for one of the great wheel.

100

LECT.

LECT. V.

Of hydroftatics, and hydraulic machines.

HE fcience of bydrostalics treats of the nature, gravity, preffure, and motion of fluids in general; and of weighing folids in them.

A fluid is a body that yields to the least pref- Definifure or difference of preffures. Its particles are tion of fo fmall, that they cannot be difcerned by the beft microfcopes; they are hard, fince no fluid. except air or fteam, can be preffed into a lefs fpace than it naturally poffeffes'; and they muft be round and fmooth, feeming they are fo eafily moved among one another.

All bodies, both fluid and folid, prefs downwards by the force of gravity : but fluids have this wonderful property, that their preffure upwards and fidewife is equal to their preffure downwards; and this is always in proportion to their perpendicular height, without any regard to their quantity; for, as each particle is quite free to move, it will move towards that part or fide on which the preffure is leaft. And hence, no particle or quantity of a fluid can be at reft, till it is every way equally preffed.

To fhew by experiment that fluids prefs up- Plate X. ward as well as downward, let A B be a long Fig. 1. upright tube filled with water near to its top; and C D a fmall tube open at both ends, and immerfed into the water in the large one; if the ward as immerfion be quick, you will fee the water rife in the fmall tube to the fame height that it ftands in the great one, or until the furfaces of the H 2 water

Fluids prefs as much updownward,

a fluid.

water in both are on the fame level : which fhews that the water is preffed upward into the fmall tube by the weight of what is in the great one; otherwife it could never rife therein, contrary to its natural gravity; unless the diameter of the bore were fo fmall, that the attraction of the tube would raife the water; which will never happen, if the tube be as wide as that in a common barometer. And, as the water rifes no higher in the fmall tube than till its furface be. on a level with the furface of the water in the great one, this fhews that the preffure is not in proportion to the quantity of water in the great tube, but in proportion to its perpendicular height therein: for there is much more water in the great tube all around the fmall one, than what is raifed to the fame height in the finall one, as it ftands within the great.

Take out the fmall tube, and let the water run out of it; then it will be filled with air. Stop its upper end with the cork C, and it will be full of air all below the cork : this done, plunge it again to the bottom of the water in the great tube, and you will fee the water rife up in it only to the height D; which fhews that the air is a body, otherwife it could not hinder the water from rifing up to the fame height as it did before, namely, to A; and in fo doing, it drove the air out at the top; but now the air is confined by the cork C: and it alfo fhews that the air is a compreffible body, for if it were not fo, a drop of water could not enter into the tube.

The prefiure of fluids being equal in all directions, it follows that the fides of a veffel are as much prefied by a fluid in it, all around in any given ring of points, as the fluid below that ring is prefied by the weight of all that flands above it.

102

it. Hence the preffure upon every point in the fides, immediately above the bottom, is equal to the preffure upon every point of the bottom. To fhew this by experiment, let a hole be made at Fig. 2. e in the fide of the tube AB close by the bottom; and another hole of the fame fize in the bottom at C; then pour water into the tube. keeping it full as long as you choose the holes fhould run, and have two bafons ready to receive the water that runs through the two holes, until you think there is enough in each bafon; and you will find by meaforing the quantities, that they are equal; which fhews that the water run with equal fpeed through both holes : which it could not have done, if it had not been equally preffed through them both. For, if a hole of the fame fize be made in the fide of the tube, as about f, and if all three are permitted to run together, you will find that the quantity run through the hole at f is much lefs than what has run in the fame time through either of the holes C or e.

In the fame figure, let a tube be turned up from the bottom at C into the fhape D E, and the hole at C be ftopt with a cork. Then, pour water into the tube to any height, as Ag, and it will fpout up in a jet E F G, nearly as high as it is kept in the tube AB, by continuing to pour in as much there as runs through the hole E; which will be the cafe whilft the furface Ag keeps at the lame height. And if a little ball of cork G be laid upon the top of the jet, it will be fupported thereby, and dance upon it. The reafon why the jet rifes not quite fo high as the furface of the water Ag, is owing to the reliftance it meets with in the open air : for, if a tube, either great or fmall, was fcrewed upon the pipe at E, the H 3 water

water would rife in it until the furface of the water in both tubes were on the fame level; as will be fhewn by the next experiment.

The bydroftatic, paradox. Any quantity of a fluid, how finall foever, may be made to balance and fupport any quantity, how great foever. This is defervedly termed the hydroftatical paradox, which we shall first shew by an experiment, and then account for it upon the principle above mentioned; namely, that the preffure of fluids is directly as their perpendicular beight, without any regard to their quantity.

Fig. 3.

Let a fmall glass tube DCG, open throughout, and bended at B, be joined to the end of a great one Al at cd, where the great one is also open ; fo that these tubes in their openings may freely communicate with each other. Then pour water through a fmall necked funnel into the fmall tube at H; this water will run through the joining of the tubes at cd, and rife up into the great tube; and if you continue pouring until the furface of the water comes to any part, as A, in the great tube, and then leave off, you will fee that the furface of the water in the fmall tube will be just as high, at D; fo that the perpendicular height of the water will be the fame in both tubes, however fmall the one be in proportion to the other. This fhews, that the fmall column DCG balances and fupports the great column Acd: which it could not do if their preffures were not equal against one another in the recurved bottom at B .- If the fmall tube be made longer, and inclined in the fituation GEF, the furface of the water in it will ftand at F, on the fame level with the furface A in the great tube; that is, the water will have the fame perpendicular height in both tubes, although the column in the fmall tube is longer than that in the great one; the the former being oblique, and the latter perpendicular.

Since then the preffure of fluids is directly as their perpendicular heights, without any regard to their quantities, it appears that whatever the figure or fize of veffels be, if they are of equal heights, and if the areas of their bottoms are equal, the preffures of equal heights of water are equal upon the bottoms of these veffels; even though the one fhould hold a thousand or ten thousand times as much water as would fill the other. To confirm this part of the hydroftatical Fig. 4, 5. paradox by an experiment, let two veffels be prepared of equal heights but very unequal contents, fuch as AB in Fig. 4. and AB in Fig. 5. Let each veffel be open at both ends, and their bottoms Dd, Dd be of equal widths. Let a brafs bottom CC be exactly fitted to each veffel, not to go into it, but for it to fland upon ; and let a piece of wet leather be put between each veffel and its brafs bottom, for the fake of clofenefs. Join each bottom to its veffel by a hinge D, fo that it may open like the lid of a box; and let each bottom be kept up to its veffel by equal weights E and E hung to lines which go over the pulleys F and F (whofe blocks are fixed to the fides of the veffels at f) and the lines tied to hooks at d and d, fixed in the brafs bottoms opposite to the hinges D and D. Things being thus prepared and fitted, hold the veffel AB (Fig. 5.) upright in your hands over a baion on a table, and caufe water to be poured into the veffel flowly, till the preffure of the water bears down its bottom at the fide d, and raifes the weight E; and then part of the water will run out at d. Mark the height at which the furface H of the water flood in the veffel, when the bot-H4 tom
tom began to give way at d; and then, holding up the other veffel A B (Fig. 4.) in the fame manner, caufe water to be poured into it at H; and you will fee that when the water rifes to Ain this veffel, just as high as it did in the former, its bottom will also give way at d, and it will lofe part of the water.

The natural reafon of this furprifing phenomenon is, that fince all parts of a fluid at equal depths below the furface are equally preffed in all manner of directions, the water immediately below the fixed part B f (Fig. 4.) will be preffed as much upward against its lower furface within the veffel, by the action of the column Ag, as it would be by a column of the fame height, and of any diameter whatever; (as was evident by the experiment with the tube, Fig. 2.) and therefore, fince action and reaction are equal and contrary to each other, the water immediately below the furface B f will be preffed as much downward by it, as if it was immediately touched and preffed by a column of the height g A, and of the diameter Bf: and therefore, the water in the cavity B D d f will be preffed as much downward upon its bottom CC, as the bottom of the other veffel (Fig. 5.) is preffed by all the water above it.

Fig. 4.

To illustrate this a little farther, let a hole be made at f in the fixed top B f, and let a tube Gbe put into it; then, if water be poured into the tube A, it will (after filling the cavity B d) rife up into the tube G, until it comes to a level with that in the tube A, which is manifeltly owing to the preffure of the water in the tube A, upon that in the cavity of the veffel below it. Confequently, that part of the top B f, in which the hole is now made, would, if corked up, be preffed

preffed upward with a force equal to the weight of all the water which is supported in the tube G: and the fame thing would hold at g, if a hole were made there. And to if the whole cover or top B f were full of holes, and had tubes as high as the middle one Ag put into them, the water in each tube would rife to the fame height as it is kept into the tube A, by pouring more into it, to make up the deficiency that it fultains by fupplying the others, until they are all full: and then the water in the tube A would support equal heights of water in all the reft of the tubes. Or, if all the tubes except A, or any other one, were taken away, and a large tube equal in diameter to the whole top Bf were placed upon it, and cemented to it, and then if water were poured into the tube that was left in either of the holes, it would afcend through all the reft of the holes, until it filled the large tube to the fame height that it ftands in the imall one, after a fufficient quantity had been poured into it: which fnews, that the top Bf was prefied upward by the water under it, and before any hole was made in it, with a force equal to that wherewith it is now preffed downward by the weight of all the water above it in the great tube. And therefore, the reaction of the fixed top Bf must be as great, in preffing the water downward upon the bottom CC, as the whole preffure of the water in the great tube would have been, if the top had been taken away, and the water in that tube left to prefs directly upon the water in the cavity B D d f.

Perhaps the beft machine in the world for Fig. 6. demonstrating the upward preffure of fluids, is The hythe hydroftatic bellows A; which confilts of two droftatic bellows. thick oval boards, each about 16 inches broad, and 18 inches long, covered with leather, to

107

open

open and thut like a common bellows, but without valves; only a pipe B, about three feet high, is fixed into the bellows at e. Let fome water be poured into the pipe at c, which will run into the bellows, and feparate the boards a little. Then lay three weights b, c, d, each weighing 100 pounds, upon the upper board, and pour more water into the pipe B, which will run into the bellows, and raife up the board with all the weights upon it; and if the pipe be kept full, until the weights are raifed as high as the leather which covers the bellows will allow them, the water will remain in the pipe, and fupport all the weights, even though it fhould weigh no more than a quarter of a pound, and they 300 pounds: nor will all their force be able to caufe them to defcend and force the water out at the top of the pipe.

The reason of this will be made evident, by confidering what has been already faid of the refult of the preffure of fluids of equal heights without any regard to the quantities. For, if a hole be made in the upper board, and a tube be put into it, the water will rife in the tube to the fame height that it does in the pipe; and would rife as high (by fupplying the pipe) in as many tubes as the board could contain holes. Now, fuppofe only one hole to be made in any part of the board, of an equal diameter with the bore of the pipe B; and that the pipe holds just a guarter of a pound of water; if a perfon claps his finger upon the hole, and the pipe be filled with water, he will find his finger to be preffed upward with a force equal to a guarter of a pound. And as the fame preffure is equal upon all equal parts of the board, each part whole area is equal to the area of the hole, will be preffed upwardwith a force equal to that of a quarter of a pound : the fum

fum of all which preffures against the under fide of an oval board 16 inches broad, and 18 inches long, will amount to 300 pounds; and therefore fo much weight will be raifed up and fupported by a quarter of a pound of water in the pipe.

Hence, if a man ftands upon the upper board, How a and blows into the bellows through the pipe B, man may he will raife himfelf upward upon the board : raife him-and the finaller the bore of the pipe is, the eafier ward by he will be able to raife himfelf. And then, by his clapping his finger upon the top of the pipe, he breath. can fupport himfelf as long as he pleafes; provided the bellows be air-tight fo as not to lofe what is blown into it.

This figure, I confess, ought to have been much larger than any other upon the plate; but it was not thought of, until all the reft were drawn; and it could not fo properly come into any other plate.

Upon this principle of the upward preffure of How folid fluids, a piece of lead may be made to fwim in lead may water, by immerfing it to a proper depth, and bemade to keeping the water from getting above it. Let wim in water. CD be a glafs tube, open throughout, and EFG a flat piece of lead, exactly fitted to the Fig. 7. lower end of the tube, not to go within it, but for it to ftand upon; with a wet leather between the lead and the tube to make close work. Let this leaden bottom be half an inch thick, and held close to the tube by pulling the packthread IHL upward at L with one hand, whilft the tube is held in the other by the upper end C. In this fituation, let the tube be immerfed in water in the glass veffel AB, to the depth of fix inches below the furface of the water at K; and then, the leaden bottom E F G will be plunged to the depth of fomewhat more than eleven times its

its own thickness: holding the tube at that depth, you may let go the thread at L; and the lead will not fall from the tube, but will be kept to it by the upward preffure of the water below it, occafioned by the height of the water at K above the level of the lead. For as lead is 11.33 times as heavy as its bulk of water, and is in this experiment immerfed to a depth fomewhat more than 11.23 times its thickness, and no water getting into the tube between it and the lead, the column of water Eabc G below the lead is preffed upward against it by the water K D E G L all around the tube; which water being a little more than 11.33 times as high as the lead is thick, is fufficient to balance and fupport the lead at the depth K E. If a little water be poured into the tube upon the lead, it will increase the weight upon the column of water under the lead, and caufe the lead to fall from the tube to the bottom of the glafs veffel, where it will lie in the fituation b d. Or, if the tube be raifed a little in the water, the lead will fall by its own weight, which will then be too great for the preffure of the water around the tube upon the column of water below it.

How light be made to lie at the bottom of water.

Let two pieces of wood be plained quite flat, fo wood may as no water may get in between them when they are put together: let one of the pieces, as b d, be cemented to the bottom of the veffel AB(Fig. 7.) and the other piece be laid flat and clofe upon it, and held down to it by a flick, whilft water is poured into the veffel; then remove the flick, and the upper piece of wood will not rife from the lower one: for, as the upper one is preffed down both by its own weight and the weight of all the water over it, whilft the contrary preffure of the water is kept off by the wood

wood under it, it will lie as ftill as a ftone would do in its place. But if it be raifed ever fo little at any edge, fome water will then get under it; which being acted upon by the water above, will immediately prefs it upward; and as it is lighter than its bulk of water, it will rife, and float upon the furface of the water.

All fluids weigh just as much in their own elements as they do in open air. To prove this by experiment, let as much fhot be put into a phial, as, when corked, will make it fink in water : and being thus charged, let it be weighed, first in air, and then in water, and the weights in both cafes wrote down. Then, as the phial hangs fuspended in water, and counterpoifed, pull out the cork, that water may run into it, and it will defcend, and pull down that end of the beam. This done, put as much weight into the oppofite fcale as will reftore the equipoife; which weight will be found to answer exactly to the additional weight of the phial when it is again weighed in air, with the water in it.

The velocity with which water fpouts out at a The velohole in the fide or bottom of a veffel, is as the city of * fquare root of the depth or diftance of the fpouting hole below the furface of the water. For, in water. order to make double the quantity of a fluid run through one hole as through another of the fame fize, it will require four times the preffure of the other, and therefore must be four times the depth of the other below the furface of the water : and for the fame reason, three times the quantity running in an equal time through the

. The fquare root of any number is that which being multiplied by itfelf produces the faid number. Thus, 2 is the square root of 4, and 3 is the square root of 9: for 2 multiplied by 2 produces 4, and 3 multiplied by 3 produces 9, &c.

fame

fame fort of hole, must run with three times the velocity, which will require nine times the preffure; and confequently must be nine times as deep below the furface of the fluid : and fo on.-To prove this by an experiment, let two pipes, as C and g, of equal fized bores, be fixed into the fide of the veffel A B; the pipe g being four times as deep below the furface of the water at b in the veffel as the pipe C is : and whilft these pipes run, let water be constantly poured into the veffel, to keep the furface ftill at the fame height. Then, if a cup that holds a pint be fo placed as to receive the water that fpouts from the pipe C, and at the fame moment a cup that holds a quart be fo placed as to receive the water that fouts from the pipe g, both cups will be filled at the fame time by their refpective pipes.

The horizontal fpc diftance fid to which water will flu fpout dic from mc pipes. the

Fig. 8.

The horizontal diffance, to which a fluid will foout from a horizontal pipe, in any part of the fide of an upright veffel below the furface of the fluid, is equal to twice the length of a perpendicular to the fide of the veffel, drawn from the mouth of the pipe to a femicircle defcribed upon the altitude of the fluid: and therefore, the fluid will fpout to the greatest distance possible from a pipe, whole mouth is at the center of the femicircle; becaufe a perpendicular to its diameter (supposed parallel to the fide of the veffel) drawn from that point, is the longeft that can poffibly be drawn from any part of the diameter to the circumference of the femicircle. Thus, if the veffel AB be full of water, the horizontal pipe D be in the middle of its fide, and the femicircle N d c b be deferibed upon Das a center, with the radius or femidiameter D g N, or D f b, the perpendicular D d to the diameter N D b is the longeft that can be drawn from

112

Fig. 8.

from any part of the diameter to the circumference Ndcb. And if the veffel be kept full, the jet G will fpout from the pipe D, to the horizontal diftance N M, which is double the length of the perpendicular D d. If two other pipes, as C and E, be fixed into the fide of the veffel at equal diffances above and below the pipe D, the perpendiculars Cc and Ee, from these pipes to the semicircle, will be equal; and the jets F and H fpouting from them will each go to the horizontal diffance NK; which is double the length of either of the equal perpendiculars C c or E H.

Fluids by their preffure may be conveyed over How wahills and vallies in bended pipes, to any height ter may not greater than the level of the fpring from veyed whence they flow. But when they are defigned over hills to be raifed higher than the fprings, forcing en- and valgines must be used; which shall be described lies. when we come to treat of pumps.

A fyphon, generally used for decanting liquors, is a bended pipe, whole legs are of unequal lengths; and the fhortest leg must always be put into the liquor intended to be decanted, that the perpendicular altitude of the column of liquor in the other leg may be longer than the column in the immerfed leg, efpecially above the furface of the water. For, if both columns were equally high in that refpect, the atmofphere, which preffes as much upward as downward, and therefore acts as much upward against the column in the leg that hangs without the veffel, as it acts downward upon the furface of the liquor in the veffel, would hinder the running of the liquor through the fyphon, even though it were brought over the bended part by fuction. So that there is nothing left to caufe 3

caufe the motion of the liquor, but the fuperior weight of the column, in the longer leg, on account of its having the greater perpendicular height.

Fig. 9.

Let D be a cup filled with water to C, and A B C a fyphon, whofe fhorter leg B C F is immerfed in the water from C to F. If the end of the other leg were no lower than the line AC_{*} which is level with the furface of the water, the fyphon would not run, even though the air fhould be drawn out of it at the mouth A. For although the fuction would draw fome water at first, yet the water would stop at the moment the fuction ceased; because the air would act as much upward against the water at A, as it acted downward for it by preffing on the furface at C. But if the leg A B comes down to G, and the air be drawn out at G by fuction, the water will immediately follow, and continue to run, until the furface of the water in the cup comes down to F; becaufe, till then, the perpendicular height of the column BAG will be greater than that of the column CB; and confequently, its weight will be greater, until the furface comes down to F; and then the fyphon will ftop, though the leg C F fhould reach to the bottom of the cup. For which reafon, the leg that hangs without the cup is always made long enough to reach below the level of its bottom; as from d to E: and then, when the fyphon is emptied of air by fuction at E, the water immediately follows, and by its continuity brings away the whole from the cup; just as pulling one end of a thread will make the whole clue follow.

If the perpendicular height of a fyphon, from the furface of the water to its bended top at B,

be

be more than 33 feet, it will draw no water, even though the other leg were much longer, and the fyphon quite emptied of air; becaufe the weight of a column of water 33 feet high is equal to the weight of as thick a column of air, reaching from the furface of the earth to the top of the atmosphere; fo that there will then be an equilibrium, and confequently, though there would be weight enough of air upon the furface C to make the water afcend in the leg CB almost to the height B, if the fyphon were emptied of air, yet that weight would not be fufficient to force the water over the bend; and therefore, it could never be brought over into the leg BAG.

Let a hole be made quite through the bottom Fig. 10. of the cup A, and the longer leg of the bended Tantalus's fyphon D E B G be cemented into the hole, fo cup. that the end D of the fhorter leg D E may almost touch the bottom of the cup within. Then, if water be poured into this cup, it will rife in the fhorter leg by its upward preffure, driving out the air all the way before it through the longer leg: and when the cup is filled above the bend of the fyphon at F, the preffure of the water in the cup will force it over the bend of the fyphon; and it will defcend in the longer leg C B G, and run through the bottom, until the cup be emptied.

This is generally called *Tantalus's cup*, and the legs of the fyphon in it are almost close together; and a little hollow flatue, or figure of a man, is fometimes put over the fyphon to conceal it; the bend E being within the neck of the figure as high as the chin. So that poor thirfty *Tantalus* flands up to the chin in water, imagining it will rife a little higher, and he I may

may drink; but inftead of that, when the water comes up to his chin, it immediately begins to defcend, and fo, as he cannot floop to follow it, he is left as much pained with thirft as ever.

The fountain at command. Plate XI. Fig. 1.

The device called the fountain at command acts upon the fame principle with the fyphon in the cup. Let two veffels A and B be joined together by the pipe C which opens into them Let A be open at top, B close both at both. top and bottom (fave only a fmall hole at b to let the air get out of the veffel B) and A be of fuch a fize, as to hold about fix times as much water as B. Let a fyphon D E F be foldered to the veffel D, fo that the part D E e may be within the yeffel, and F without it; the end Dalmost touching the bottom of the vessel, and the end F below the level of D: the vefiel Bhanging to A by the pipe C (foldered into both) and the whole supported by the pillars G and Hupon the ftand I. The bore of the pipe muft be confiderably lefs than the bore of the fyphon.

The whole being thus conftructed, let the vefiel A be filled with water, which will run through the pipe C, and fill the vefiel B. When B is filled above the top of the fyphon at E, the water will run through the fyphon, and be difcharged at F. But as the bore of the fyphon is larger than the bore of the pipe, the fyphon will run fafter than the pipe, and will foon empty the vefiel B; upon which the water will ceafe from running through the fyphon at F, until the pipe C re-fills the vefiel B, and then it will begin to run as before. And thus the fyphon will continue to run and ftop alternately, until all the water in the vefiel A has run through

through the pipe C .- So that after a few trials, one may eafily guess about what time the fyphon will ftop, and when it will begin to run ; and then, to amufe others, he may call out flop, or run, accordingly.

Upon this principle, we may eafily account Intermitfor intermitting or reciprocating springs. Let ing AA be part of a hill, within which there is a prings. cavity BB; and from this cavity a vein or Fig. 2. channel running in the direction BCDE. The rain that falls upon the fide of the hill will fink and ftrain through the fmall pores and cranies G. G. G. G; and fill the cavity with water K. When the water rifes to the level HHC, the vein BCDE will be filled to C, and the water will run through CDF as through a fyphon; which running will continue until the cavity be emptied, and then it will ftop until the cavity be filled again.

The common pump (improperly called the fuck- The coming pump), with which we draw water out of mon pump. wells, is an engine both pneumatic and hydraulic. It confifts of a pipe open at both ends, in which is a moveable pifton or bucket, as big as the bore of the pipe in that part wherein it works; and is leathered round, fo as to fit the bore exactly; and may be moved up and down, without fuffering any air to come between it and the pipe or pump barrel.

We shall explain the construction both of this and the forcing-pump by pictures of glafs models, in which both the action of the piftons and motion of the valves are feen.

Hold the model DCBL upright in the veffel Fig. 3. of water K, the water being deep enough to rife at least as high as from A to L. The valve a on the moveable bucket G, and the valve b on

on the fixed box H, (which box quite fills the bore of the pipe or barrel at H) will each lie clofe, by its own weight, upon the hole in the bucket and box, until the engine begins to work. The valves are made of brafs, and lined underneath with leather for covering the holes the more clofely: and the bucket G is raifed and deprefied alternately by the handle Eand rod Dd, the bucket being fuppofed at Bbefore the working begins.

Take hold of the handle E, and thereby draw up the bucket from B to C, which will make room for the air in the pump all the way below the bucket to dilate itfelf, by which its fpring is weakened, and then its force is not equivalent to the weight or preffure of the outward air upon the water in the veffel K: and therefore, at the first stroke, the outward air will prefs up the water through the notched foot A, into the lower pipe, about as far as e: this will condense the rarefied air in the pipe between e and C to the fame flate it was in before; and then, as its fpring within the pipe is equal to the force or preffure of the outward air, the water will rife no higher by the first ftroke; and the valve b, which was raifed a little by the dilatation of the air in the pipe, will fall, and ftop the hole in the box H; and the furface of the water will ftand at e. Then, depress the pifton or bucket from C to B, and as the air in the part B cannot get back again through the valve b, it will (as the bucket defeends) raife the valve a, and fo make its way through the upper part of the barrel d into the open air. But upon raifing the bucket G a fecond time, the air between it and the water in the lower pipe at a will be again left at liberty to fill

fill a larger space; and so its spring being again weakened, the preffure of the outward air on the water in the veffel K will force more water up into the lower pipe from e to f; and when the bucket is at its greatest height C, the lower valve b will fall, and ftop the hole in the box H as before. At the next ftroke of the bucket or pifton, the water will rife through the box H towards B, and then the valve b, which was raifed by it, will fall when the bucket G is at its greateft height. Upon depreffing the bucket again, the water cannot be pulhed back through the valve b, which keeps close upon the hole whilft the pifton defcends. And upon raifing the pifton again, the outward preffure of the air will force the water up through *H*, where it will raife the valve, and follow the bucket to C. Upon the next depression of the bucket G, it will go down into the water in the barrel B; and as the water cannot be driven back through the now close valve b, it will raife the valve a as the bucket defcends, and will be lifted up by the bucket when it is next raifed. And now, the whole fpace below the bucket being full, the water above it cannot fink when it is next depreffed; but upon its depreffion, the valve a will rife to let the bucket go down ; and when it is guite down, the valve a will fall by its weight, and ftop the hole in the bucket. When the bucket is next raifed, all the water above it will be lifted up, and begin to run off by the pipe F. And thus, by raifing and depreffing the bucket alternately, there is ftill more water railed by it; which getting above the pipe F, into the wide top I, will fupply the pipe, and make it run with a continued Aream.

I 3

So,

So, at every time the bucket is raifed, the value b rifes, and the value a falls; and at every time the bucket is depressed, the value b falls, and a rifes.

As it is the preffure of the air or atmosphere which causes the water to rife, and follow the pifton or bucket G as it is drawn up; and fince a column of water 33 feet high is of equal weight with as thick a column of the atmofphere, from the earth to the very top of the air; therefore, the perpendicular height of the pifton or bucket from the furface of the water in the well must always be leis than 33 feet; otherwife the water will never get above the bucket. But, when the height is lefs, the preffure of the atmosphere will be greater than the weight of the water in the pump, and will therefore raife it above the bucket: and when the water has once got above the bucket, it may be lifted thereby to any height, if the rod D be made long enough, and a fufficient degree of ftrength be employed, to raife it with the weight of the water above the bucket.

The force required to work a pump, will be as the height to which the water is raifed, and as the fquare of the diameter of the pump-bore, in that part where the pifton works. So that, if two pumps be of equal heights, and one of them be twice as wide in the bore as the other, the wideft will raife four times as much water as the narroweft; and will therefore require four times as much firength to work it.

The widenefs or narrownefs of the pump, in any other part befides that in which the pifton works, does not make the pump either more or lefs difficult to work, except what difference may arife from the friction of the water in the bore :

bore; which is always greater in a narrow bore than in a wide one, becaufe of the greater velocity of the water.

The pump-rod is never raifed directly by fuch a handle as E at the top, but by means of a lever, whofe longer arm (at the end of which the power is applied) generally exceeds the length of the fhorter arm five or fix times; and, by that means, it gives five or fix times as much advantage to the power. Upon these principles, it will be easy to find the dimensions of a pump that shall work with a given force, and draw water from any given depth. But, as thefe calculations have been generally neglected by pump-makers (either for want of fkill or induftry) the following table was calculated by the late ingenious Mr. Booth for their benefit*. In this calculation, he fuppofed the handle of the pump to be a lever increasing the power five times; and had often found that a man can work a pump four inches diameter, and 30 feet high, and discharge 27 gallons of water (Englifh wine measure) in a minute. Now, if it be required to find the diameter of a pump, that shall raife water with the fame eafe from any other height above the furface of the well; look for that height in the first column, and overagainst it in the fecond you have the diameter or width of the pump; and in the third, you find the quantity of water which a man of ordinary ftrength can difcharge in a minute.

• I have taken the liberty to make a few alterations in Mr. Booth's numbers in the table, and to lengthen it out from 80 feet to 100.

Fig. 4. The forcingpump. The forcing pump raifes water through the box H in the fame manner as the fucking-pump does, when the plunger or pifton g is lifted up by the rod D d. But this plunger has no hole through it, to let the water in the barrel BC get above it, when it is depressed to B, and the value b (which rose by the ascent of the water

water through the box H when the plunger g was drawn up) falls down and ftops the hole in H, the moment that the plunger is raifed to its greatest height. Therefore, as the water between the plunger g and box H can neither get through the plunger upon its defcent, nor back again into the lower part of the pump Le, but has a free paffage by the cavity around H into the pipe M.M., which opens into the air-veffel KK at P; the water is forced through the pipe M M by the defcent of the plunger, and driven into the air-vefiel; and in running up through the pipe at P, it opens the valve a; which fhuts at the moment the plunger begins to be raifed, becaufe the action of the water against the under fide of the valve then ceafes.

The water, being thus forced into the airweffel KK by repeated ftrokes of the plunger, gets above the lower end of the pipe GHI, and then begins to condenfe the air in the veffel KK. For, as the pipe GH is fixed air-tight into the veffel below F_{2} and the air has no way to get out of the veffel but through the mouth of the pipe at I, and cannot get out when the mouth 1 is covered with water, and is more and more condenfed as the water rifes upon the pipe, the air then begins to act forcibly by its lpring against the furface of the water at H: and this action drives the water up through the pipe IIIGF, from whence it fpouts in a jet S to a great height; and is supplied by alternately raifing and depretting of the plunger g, which conftantly forces the water that it raifes through the valve H, along the pipe MM, into the airveffel K K.

The higher that the furface of the water H is raifed in the air-veffel, the lefs fpace will the air air be condenfed into, which before filled that veffel; and therefore the force of its fpring will be fo much the flronger upon the water, and will drive it with the greater force through the pipe at F: and as the fpring of the air continues whilf the plunger g is rifing, the ftream or jet S will be uniform, as long as the action of the plunger continues: and when the valve bopens, to let the water follow the plunger upward, the valve a fluts, to hinder the water, which is forced into the air veffel, from running back by the pipe MM into the barrel of the pump.

If there was no air-veffel to this engine, the pipe GHI would be joined to the pipe MMNat P; and then, the jet S would ftop every time the plunger is raifed, and run only when the plunger is depreffed.

Mr. Newsham's water-engine, for extinguishing fire, confifts of two forcing-pumps, which alternately drive water into a close vefiel of air; and by forcing the water into that vefiel, the air in it is thereby condensed, and compress the water fo ftrongly, that it rufhes out with great impetuosity and force through a pipe that comes down into it; and makes a continued uniform stream by the condensation of the air upon its furface in the vessel.

By means of forcing-pumps, water may be raifed to any height above the level of a river or fpring; and machines may be contrived to work thefe pumps, either by a running ftream, a fall of water, or by horfes. An inftance in each fort will be fufficient to fhew the method.

Firft,

J. Mynde feulp .

First, by a running stream, or a fall of wa- Plate XII. ter. Let AA be a wheel, turned by the fall Fig. 1. of water BB; and have any number of cranks (fuppofe fix) as C, D, E, F, G, H, on its axis. according to the ftrength of the fall of water. and the height to which the water is intended to be raifed by the engine. As the wheel turns round, these cranks move the levers c, d, e, f, g, b A pump up and down, by the iron rods i, k, l, m, n, o; engine to which alternately raife and deprefs the piftons by go by the other iron rods p, q, r, f, t, u, w, x, y, in twelve pumps; nine whereof, as L, M, N, O, P, 2, R, S, T, appear in the plate; the other three being hid behind the work at V. And as pipes may go from all these pumps, to convey the water (drawn up by them to a fmall height) into a close ciftern, from which the main pipe goes off, the water will be forced into this ciftern by the defcent of the piltons. And as each pipe, going from its refpective pump into the ciftern, has a valve at its end in the ciftern, these valves will hinder the return of the water by the pipes; and therefore, when the ciftern is once full, each pifton upon its defcent will force the water (conveyed into the ciftern by a former stroke) up the main pipe, to the height the engine was intended to raife it: which height depends upon the quantity raifed, and the power that turns the wheel. When the power upon the wheel is leffened by any defect of the quantity of water turning it, a proportionable number of the pumps may be fet alide, by difengaging their rods from the vibrating levers.

This figure is a reprefentation of the engine erected at Blenheim for the Duke of Marlborough, by the late ingenious Mr. Aldersea. The waterwheel

wheel is 77 feet in diameter, according to Mr. Switzer's account in his Hydraulics. 1733

When fuch a machine is placed in a ftream that runs upon a fmall declivity, the motion of the levers and action of the pumps will be but flow; fince the wheel must go once round for each ftroke of the pumps. But, when there is a large body of flow running water, a cog or fpurwheel may be placed upon each fide of the water-wheel AA, upon its axis, to turn a trundle upon each fide; the cranks being upon the axis of the trundle. And by proportioning the cogwheels to the trundles, the motion of the pumps may be made quicker, according to the quantity and ftrength of the water upon the first wheel; which may be as great as the workman pleafes; according to the length and breadth of the floatboards or wings of the wheel. In this manner, the engine for raifing water at London-Bride is constructed; in which, the water-wheel is 20 feet diameter, and the floats 14 feet long.

A pumpgo by horfes.

Fig. 2.

Where a ftream or fall of water cannot be had, engine to and gentlemen want to have water raifed, and brought to their houfes from a rivulet or fpring; this may be effected by a horfe-engine, working three forcing pumps which ftand in a refervoir filled by the fpring or rivulet: the piftons being moved up and down in the pumps by means of a triple crank ABC, which, as it is turned round by the trundle G, raifes and depreffes the rods D, E, F. The trundle may be turned by fuch a wheel as F in Fig. 1. of Plate VIII, having levers y,y,y,y, on its upright axle, to which horfes may be joined for working the engine. And if the wheel has three times as many cogs as the trundle has flaves or rounds, the trundle and cranks will make three revolutions for every one of

of the wheel; and as each crank will fetch a ftroke in the time it goes round, the three cranks will make nine ftrokes for every turn of the great wheel.

The cranks fould be made of caft iron, because that will not bend; and they should each make an angle of 120 with both of the others. as at a,b,c; which is (as it were) a view of their plate XII. radii, in looking endwife at the axis: and then Fig. 2. there will be always one or other of them going downward, which will push the water forward with a continued ftream into the main pipe. For, when b is almost at its lowest position, and is therefore just beginning to lose its action upon the pifton which it moves, c is beginning to move downward, which will by its pifton continue the propelling force upon the water: and when c is come down to the polition of b, a will be in the polition of c.

The more perpendicularly the pifton rods move up and down in the pumps, the freer and better will their strokes be: but a little deviation from the perpendicular will not be material. Therefore, when the pump-rods D, E, and F go down into a deep well, they may be moved directly by the cranks, as is done in a very good horfe-engine of this fort at the late Sir James Creed's at Greenwich, which forces up water about 64 feet from a well under ground, to a refervoir on the top of his houfe. But when the cranks are only at a finall height above the pumps, the piftons must be moved by vibrating levers, as in the above engine at Blenbeim : and the longer the levers are, the nearer will the ftrokes be to a perpendicular.

Let us suppose, that in such an engine as Sir A calcu-James Creed's, the great wheel is 12 feet diame- lation of ter, the trundle 4 feet, and the radius or length the quanof tity of

may be raifed by a horfeengine.

128

water that of each crank 9 inches, working a pifton in its pump. Let ther be three pumps in all, and the bore of each pump be four inches diameter. Then, if the great wheel has three times as many cogs as the trundle has flaves, the trundle and cranks will go three times round for each revolution of the horfes and wheel, and the three cranks will make nine ftrokes of the pumps in that time, each ftroke being 18 inches (or double the length of the crank) in a four-inch bore. Let the diameter of the horfe-walk be 18 feet, and the perpendicular height to which the water is raifed above the furface of the well be 64 feet.

> If the horfes go at the rate of two miles an hour (which is very moderate walking) they will turn the great wheel 187 times round in an hour.

> In each turn of the wheel the piftons make q ftrokes in the pumps, which amount to 1683 in an hour.

> Each stroke raises a column of water 18 inches long, and four inches thick, in the pump-barrels; which column, upon the defcent of the pifton, is forced into the main pipe, whole perpendicular altitude above the furface of the well is 64 feet.

> Now, fince a column of water 18 inches long, and 4 inches thick, contains 226.18 cubic inches. this number multiplied by 1683 (the ftrokes in an hour gives 280661 for the number of cubic inches of water railed in an hour.

> A gallon, in wine measure, contains 231 cubic inches, by which divide 380661, and it quotes 1468 in round numbers, for the number of gallons raifed in an hour; which, divided by 63, gives 261 hogheads. - If the horfes go fatter, the quantity raifed will be fo much the greater.

In this calculation it is fuppoied that no water is

is walted by the engine. But as no forcing engine can be supposed to lose less than a fifth part of the calculated quantity of water, between the pistons and barrels, and by the opening and shutting of the valves, the hoss ought to walk almost $2\frac{1}{2}$ miles per hour, to fetch up this loss.

A column of water 4 inches thick, and 64 feet high, weighs $349\frac{9}{16}$ pounds avoirdupoife, or $424\frac{5}{12}$ pounds troy; and this weight together with the friction of the engine, is the refiftance that muft be overcome by the ftrength of the horfes.

The horfe-tackle fhould be to contrived, that the horfes may rather puth on than drag the levers after them. For if they draw, in going round the walk, the outfide leather thraps will rub against their fides and hams; which will hinder them from drawing at right angles to the levers, and fo make them pull at a diladvantage. But if they puth the levers before their breafts, inftead of dragging them, they can always walk at right angles to thefe levers.

It is no ways material what the diameter of the main or conduct pipe be: for the whole refiftance of the water therein, against the horfes will be according to the height to which it is raifed, and the diameter of that part of the pump in which the pifton works, as we have already obferved. So that by the fame pump, an equal quantity of water may be raifed in (and confequently made to run from) a pipe of a foot diameter, with the fame eafe as in a pipe of five or fix inches: or rather with more eafe, because its velocity in a large pipe will be lefs than in a fmall one; and therefore its friction against the fides of the pipe will be lefs alfo.

And the force required to raife water depends not upon the length of the pipe, but upon the perpendicular height to which it is raifed therein above

Fig. 3.

above the level of the fpring. So that the fame force, which would raife water to the height ABin the upright pipe AiklmnopqB, will raife it to the fame height or level BIH in the oblique pipe AEFGH. For the preflure of the water at the end A of the latter, is no more that its preffure against the end A of the former.

The weight or preffure of water at the lower end of the pipe, is always as the fine of the angle to which the pipe is elevated above the level parallel to the horizon. For, although the water in the upright pipe AB would require a force applied immediately to the lower end A equal to the weight of all the water in it, to fupport the water, and a little more to drive it up, and out of the pipe; yet, if that pipe be inclined from its upright polition to an angle of 80 degrees (as in A 80) the force required to support or to raife the fame cylinder of water will then be as much lefs, as the fine 80 b is lefs than the radius AB; or as the fine of 80 degrees is lefs than the fine of 90. And fo, decreafing as the fine of the angle of elevation leffens, until it arrives at its level AC or place of reft, where the force of the water is nothing at either end of the pipe. For, although the abfolute weight of the water is the fame in all politions, yet its preffure at the lower end decreafes, as the fine of the angle of elevation decreases; as will appear plainly by a farther confideration of the figure.

Let two pipes, AB and AC, of equal lengths and bores, join each other at A; and let the pipe AB be divided into 100 equal parts, as the fcale S is; whofe length is equal to the length of the pipe.—Upon this length, as a radius, defcribe the quadrant BCD, and divide it into go equal parts or degrees.

Let the pipe AC be elevated to 10 degrees upon

upon the quadrant, and filled with water; then, part of the water that is in it will rife in the pipe AB, and if it be kept full of water, it will raife the water in the pipe AB from A to i; that is, to a level i 10 with the mouth of the pipe at 10: and the upright line a 10, equal to Ai, will be the fine of 10 degrees elevation; which being measured upon the fcale S, will be about 17.4 of fuch parts as the pipe contains 100 in length: and therefore, the force or preffure of the water at A, in the pipe A 10, will be to the force or preflure at A in the pipe AB, as 17.4 to 100.

Let the fame pipe be elevated to 20 degrees in the quadrant, and if it be kept full of water, part of that water will run into the pipe AB, and rife therein to the height Ak, which is equal to the length of the upright line b 20, or to the fine of 20 degrees elevation; which, being measured upon the scale S, will be 34.2 of such parts as the pipe contains 100 in length. And therefore, the preffure of the water at A, in the full pipe A 20, will be to its preffure, if that pipe were raifed to the perpendicular fituation AB, as 34.2 to 100.

Elevate the pipe to the polition A 30 on the quadrant, and if it be fupplied with water, the water will rife from it, into the pipe AB, to the height Al, or to the fame level with the mouth of the pipe at 30. The fine of this elevation, or of the angle of 30 degrees, is c 30; which is juft equal to half the length of the pipe, or to 50 of fuch parts of the fcale, as the length of the pipe contains 100. Therefore, the prefute of the water at A, in a pipe elevated 30 degrees above the horizontal level, will be equal to one half of what it would be, if the fame pipe flood upright in the fituation AB.

And

And thus, by elevating the pipe to 40, 50, 60, 70, and 80 degrees on the quadrant, the fines of these elevations will be d 40, e 50, f 60, g 70, and b 80; which will be equal to the heights Am, An, Ao, Ap, and Aq: and these

heights

heights meafured upon the fcale S will be 64.3, 76.6, 86.6, 94.0, and 98.5; which express the preffures at \mathcal{A} in all these elevations, confidering the preffure in the upright pipe \mathcal{AB} as 100.

Becaufe it may be of ufe to have the lengths of all the fines of a quadrant from o degrees to 90, we have given the foregoing table, flewing the length of the fine of every degree in fuch parts as the whole pipe (equal to the radius of the quadrant) contains 1000. Then the fines will be integral or whole parts in length. But if you fuppofe the length of the pipe to be divided only into 100 equal parts, the laft figure of each part or fine muft be cut off as a decimal; and then those which remain at the left hand of this feparation will be integral or whole parts.

Thus, if the radius of the quadrant (fuppofed to be equal to the length of the pipe AC) be divided into 1000 equal parts, and the elevation be 45 degrees, the fine of that elevation will be equal to 707 of thefe parts : but if the radius be divided only into 100 equal parts, the fame fine will be only 70.7 or 70_{10}^{7} of thefe parts. For, as 1000 is to 707, fo is 100 to 70.7.

As it is of great importance to all enginemakers, to know what quantity and weight of water will be contained in an upright round pipe of a given diameter and height; fo as by knowing what weight is to be raifed, they may proportion their engines to the force which they can afford to work them; we fhall fubjoin tables fhewing the number of cubic inches of water contained in an upright pipe of a round bore, of any diameter from one inch to fix and

K 2

a half;

a half; and of any height from one foot to two hundred: together with the weight of the faid number of cubic inches, both in troy and avoirdupoife ounces. The number of cubic inches divided by 231, will reduce the water to gallons in wine measure; and divided by 282, will reduce it to the measure of ale gallons. Also, the troy ounces divided by 12, will reduce the weight to troy pounds; and the avoirdupoife ounces divided by 16, will reduce the weight to avoirdupoife pounds.

And here I must repeat it again, that the weight or preffure of the water acting against the power that works the engine, must always be effimated according to the perpendicular height to which it is to be raifed, without any regard to the length of the conduct-pipe, when it has an oblique polition; and as if the diameter of that pipe were just equal to the diameter of that part of the pump in which the pifton works. Thus, by the following tables, the preffure of the water, against an engine whole pump is of a 41 inch bore, and the perpendicular height of the water in the conduct-pipe is 80 feet, will be equal to 8057.5 troy ounces, and to 8848.2 avoirdupoife ounces; which makes 671.4 troy pounds, and 553 avoirdupole.

For any bore whole diameter exceeds $6\frac{1}{2}$ inches, multiply the numbers on the following page, against any height, (belonging to 1 inch diameter) by the square of the diameter of the given bore, and the products will be the number of cubic inches, troy ounces, and avoirdupoife ounces of water, that the given bore will contain.

The folidity of cylinders are found by multiplying the areas of their bafes by their altitudes. And ARCHIMEDES gives the following proportion for finding the area of a circle, and the folidity of a cylinder raifed upon that circle:

power of the engine must be fufficient for the weight of the rod, in order to bring it up.

2. It is known, that the atmosphere preffes upon the furface of the earth with a force equal to 15 pounds upon every fquare inch.

3. When

3. When water is heated to a certain degree, the particles thereof repel one another, and confitute an elastic fluid, which is generally called *fteam* or *vapour*.

4. Hot fteam is very elaftic; and when it is cooled by any means, particularly by its being mixed with cold water, its elafticity is deftroyed immediately, and it is reduced to water again.

5. If a vefiel be filled with hot fleam, and then clofed, fo as to keep out the external air, and all other fluids; when that fleam is by any means condenfed, cooled, or reduced to water, *that* water will fall to the bottom of the vefiel; and the cavity of the vefiel will be almost a perfect vacuum.

6. Whenever a vacuum is made in any veffel, the air by its weight will endeavour to rufh into the veffel, or to drive in any other body that will give way to its preffure; as may be eafily feen by a common fyringe. For, if you ftop the bottom of a fyringe, and then draw up the pifton, if it be fo tight as to drive out all the air before it, and leave a vacuum within the fyringe, the pifton being let go will be driven down with a great force.

7. The force with which the pifton is driven down, when there is a vacuum under ir, will be as the fquare of the diameter of the bore in the fyringe. That is to fay, it will be driven down with four times as much force in a fyringe of a two-inch bore, as in a fyringe of one inch: for the areas of circles are always as the fquares of their diameters.

8. The preffure of the atmosphere being equal to 15 pounds upon a fquare inch, it will be almost equal to 12 pounds upon a circular inch. So that if the bore of the fyringe L be

be round, and one inch in diameter, the piftonwill be preft down into it by a force nearly equal to 12 pounds: but if the bore be two inches diameter, the pifton will be preft down with four times that force.

And hence it is eafy to find with what force the atmosphere preffes upon any given number either of iquare or circular inches.

These being the principles upon which this engine is constructed, we shall next describe the chief working parts of it: which are, 1. A boiler. 2. A cylinder and piston. 3. A beam or lever.

The *boiler* is a large veffel made of iron or copper; and commonly fo big as to contain about 2000 gallons.

The cylinder is about 40 inches diameter, bored fo fmooth, and its leathered pifton fitting fo clofe, that little or no water can get between the pifton and fides of the cylinder.

Things being thus prepared, the cylinder is placed upright, and the fhank of the pifton is fixed to one end of the *beam*, which turns on a center like a common balance.

The boiler is placed under the cylinder, with a communication between them, which can be opened and thut occafionally.

The boiler is filled about half full of water, and a ftrong fire is placed under it: then, if the communication between the boiler and the cylinder be opened, the cylinder will be filled with hot fteam; which would drive the pifton quite out at the top of it. But there is a contrivance by which the beam, when the pifton is near the top of the cylinder, fluts the communication at the top of the boiler within.

148

This

This is no fooner thut, than another is opened by which a little cold water is thrown upwards in a jet into the cylinder, which mixing with the hot fleam, condenfes it immediately; by which means a vacuum is made in the cylinder, and the pifton is preffed down by the weight of the atmosphere; and so lifts up the loaded pumprod at the other end of the beam.

If the cylinder be 42 inches in diameter, the pifton will be prefied down with a force greater than 20000 pounds, and will confequently lift up that weight at the opposite end of the beam: and as the pump-rod with its plunger is fixed to that end, if the bore where the plunger works were 10 inches diameter, the water would be forced up through a pipe of 180 yards perpendicular height.

But, as the parts of this engine have a good deal of friction, and muft work with a confiderable velocity, and there is no fuch thing as making a perfect vacuum in the cylinder, it is found that no more than 8 pounds of preffure muft be allowed for, on every circular inch of the pifton in the cylinder, that it may make about 16 ftrokes in a minute, about 6 feet each.

Where the boiler is very large, the pifton will make between 20 and 25 ftrokes in a minute, and each ftroke 7 or 8 feet; which, in a pump of 9 inches bore, will raife upwards of 300 hogfheads of water in an hour.

It is found by experience that a cylinder, 40 inches diameter, will work a pump 10 inches diameter, and 100 yards long: and hence we can find the diameter and length of a pump, that can be worked by any other cylinder.

L 2

For

For the convenience of those who would make use of this engine for raising water, we thall subjoin part of a table calculated by Mr. *Beighton*, shewing how any given quantity of water may be railed in an hour, from 48 to 440 hogsheads; at any given depth, from 15 to 100 yards; the machine working at the rate of 16 strokes per minute, and each stroke being 6 feet long.

One example of the ufe of this table will make the whole plain. Suppofe it were required to draw 150 hogfheads per hour, at 90 yards depth; in the fecond column from the right hand, I find the neareft number, viz. 149 hogfheads 40 gallons, againft which, on the right hand, I find the diameter of the bore of the pump muft be 7 inches; and in the fame collateral line, under the given depth 90, I find 27 inches, the diameter of the cylinder fit for that purpofe.— And fo for any other.

L 3 Water						

fian wheel.

152

PlateXIII. Water may be raifed by means of a ftream The Per- AB turning a wheel CDE, according to the order of the letters, with buckets a, a, a, a, &c. hung upon the wheel by ftrong pins b, b, b, b, &c. fixed in the fide of the rim : but the wheel must be made as high as the water is intended to be raifed above the level of that part of the ftream in which the wheel is placed. As the wheel turns, the buckets on the right-hand go down into the water, and are filled therewith, and go up full on the left-hand, until they come to the top at K; where they thrike against the end n of the fixed trough M, and are thereby overfet, and empty the water into the trough; from which it may be conveyed in pipes to the place which it is defigned for : and as each bucket gets over the trough, it falls into a perpendicular pofition again, and goes down empty, until it comes to the water at A, where it is filled as before. On each bucket is a fpring r. which going over the top or crown of the bar m (fixed to the trough M) raifes the bottom of the bucket above the level of its mouth, and fo caufes it to empty all its water into the trough.

> Sometimes this wheel is made to raife water no higher than its axle; and then, instead of buckets hung upon it, its fpokes C, d, e, f, g, b, . are made of a bent form, and hollow within; thefe hollows opening into the holes C, D, E, F. in the outfide of the wheel, and alfo into those at O in the box N upon the axle. So that, as the holes C, D, &c. dip into the water, it runs into them; and as the wheel turns, the water rifes in the hollow spokes, c, d, &c. and runs out in a stream P from the holes at O, and falls into the trough 2, from whence it is conveyed by pipes. And this is a very eafy way of railing water,

water, because the engine requires no animal power to turn it.

The art of weighing different bodies in water, O' the and thereby finding their specific gravities, or specific weights, bulk for bulk, was invented by AR- gravities CHIMEDES; of which we have the following of bodies. account :

Hiero king of Syracule, having employed a goldfmith to make a crown, and given him a mais of pure gold for that purpole, fulpected that the workman had kept back part of the . gold for his own ufe, and made up the weight by allaying the crown with copper. But the king not knowing how to find out the truth of that matter, referred it to Archimedes; who having studied a long time in vain, found it out at last by chance. For, going into a bathingtub of water, and observing that he thereby raifed the water higher in the tub than it was before, he concluded inftantly that he had raifed is just as high as any thing elfe could have done, that was exactly of his bulk : and confidering that any other body of equal weight, and of lefs bulk than himfelf, could not have raifed the water fo high as he did; he immediately told the king, that he had found a method by which he could difcover whether there were any cheat in the crown. For, fince gold is the heaviest of all known metals, it mult be of lefs bulk, according to its weight, than any other metal. And therefore he defired that a mafs of pure gold, equally heavy with the crown when weighed in air, fhould be weighed againft it in water; and if the crown was not allayed, it would counterpoife the mais of gold when they were both immerfed in water, as well as it did when they were weighed in air. But upon making 1.4

making the trial, he found that the mafs of gold weighed much heavier in water than the crown did: And not only fo, but that, when the mais and crown were immeried feparately in one vefiel of water, the crown raifed the water much higher than the mais did; which fhewed it to be allayed with fome ligher metal that increased its bulk. And fo, by making trials with different metals, all equally heavy with the crown when weighed in air, he found out the quantity of alloy in the crown,

The fpecific gravities of bodies are as their weights, bulk for bulk; thus a body is faid to have two or three times the fpecific gravity of another, when it contains two or three times as much matter in the fame space.

A body immerfed in a fluid will fink to the bottom, if it be heavier than its bulk of the fluid. If it be fuspended therein, it will lofe as much of what it weighed in air, as its bulk of the fluid weighs. Hence, all bodies of equal bulks, which would fink in fluids, lofe equal weights when fufpended therein. And unequal bodies lofe in proportion to their bulks.

The bydroftatic balance.

The bydroftatic balance differs very little from a common balance that is nicely made: only it has a hook at the bottom of each fcale, on which finall weights may be hung by horfehairs, or by filk threads. So that a body, fufpended by the hair or thread, may be immerfed in water without wetting the fcale from which it hangs.

How to. any body.

If the body thus fufpended under the fcale, find the at one end of the balance, be first counterpoifed gravity of in air by weights in the oppolite fcale, and then immerfed in water, the equilibrium will be immediately deftroyed. Then, if as much weight

be

be put into the fcale from which the body hangs, as will reftore the equilibrium (without altering the weights in the opposite scale) that weight, which reftores the equilibrium, will be equal to the weight of a quantity of water as big as the immerfed body. And if the weight of the body in air be divided by what it lofes in water, the quotient will flew how much that body is heavier than its bulk of water. Thus, if a guinea fuspended in air, be counterbalanced by 129 grains in the oppofite fcale of the balance; and then, upon its being immerfed in water, it becomes fo much lighter, as to require 74 grains put into the scale over it, to reftore the equilibrium, it fhews that a quantity of water, of equal bulk with the guinea, weighs 71 grains, or 7.25; by which divide 129 (the weight of the guinea in air) and the quotient will be 17.793; which shews that the guinea is 17.793 times as heavy as its bulk of water. And thus, any piece of gold may be tried, by weighing it first in air, and then in water; and if upon dividing the weight in air by the loss in water, the quotient comes out to be 17.703, the gold. is good; if the quotient be 18, or between 18 and 19, the gold is very fine; but if it be lefs than 17, the gold is too much allayed, by being mixed with fome other metal.

If filver be tried in this manner and found to be 11 times as heavy as water, it is very fine; if it be $10\frac{1}{2}$ times as heavy, it is flandard; but if it be of any lefs weight compared with water, it is mixed with fome lighter metal, fuch as tin.

By this method, the fpecific gravities of all bodies that will fink in water, may be found. But as to those which are lighter than water, as most

most forts of wood are, the following method may be taken, to shew how much lighter they are than their respective bulks of water.

Let an upright flud be fixed into a thick flat piece of brafs, and in this flud let a fmall lever, whole arms are equally long, turn upon a fine pin as an axis. Let the thread which hangs from the scale of the balance be tied to one end of the lever, and a thread from the body to be weighed, tied to the other end. This done, put the brafs and lever into a veffel; then pour water into the veffel, and the body will rife and float upon it, and draw down the end of the balance from which it hangs: then, put as much weight in the oppofite fcale as will raife that end of the balance, fo as to pull the body down into the water by means of the lever; and this weight in the fcale will fhew how much the body is lighter than its bulk of water.

There are fome things which cannot be weighed in this manner, fuch as quickfilver, fragments of diamonds, &c. becaufe they cannot be fufpended in threads; and must therefore be put into a glass bucket, hanging by a thread from the hook of one fcale, and counterpoifed by weights put into the opposite scale. Thus, fuppole you want to know the fpecific gravity of quickfilver, with respect to that of water; let the empty bucket be first counterpoifed in air, and then the quickfilver put into it and weighed. Write down the weight of the bucket, and alfo of the quickfilver; which done, empty the bucket, and let it be immerfed in water as it hangs by the thread, and counterpoifed therein by weights in the opposite fcale : then, pour the quickfilver into the bucket in the water, which will cause it to preponderate; and put as much

much weight into the opposite fcale as will reftore the balance to an equipoife; and this weight will be the weight of a quantity of water equal in bulk to the quickfilver. Laftly, divide the weight of the quickfilver in air, by the weight of its bulk of water, and the quotient will shew how much the quickfilver is heavier than its bulk-of water.

If a piece of brafs, glafs, lead, or filver, be immerfed and fulpended in different forts of fluids, the different loffes of weight therein will fhew how much it is heavier than its bulk of the fluid; the fluid being lighteft in which the immerfed body lofes leaft of its aerial weight. A folid bubble of glafs is generally used for finding the fpecific gravities of fluids.

Hence we have an eafy method of finding the fpecific gravities both of folids and fluids, with regard to their fpecific bulks of common pump water, which is generally made a ftandard for comparing all others by.

In conftructing tables of fpecific gravities with accuracy, the gravity of water must be reprefented by unity or 1.000, where three cyphers are added, to give room for expressing the ratios of other gravities in decimal parts, as in the following table.

N. B. Although guinea gold has been generally reckoned 17.798 times as heavy as its bulk of water, yet, by many repeated trials, I cannot fay that I have found it to be more than $17.200 (\text{or } 17\frac{2}{10})$ as heavy.

Take away the decimal points from the numbers in the right-hand column, or (which is the fame) multiply them by 1000, and they will fhew how many avoirdupoife ounces are contained in a cubic foot of each body.

The use of the table of specific gravities will How to best appear by an example. Suppose a body to find out be compounded of gold and filver, and it is re- the quanquired to find the quantity of each metal in adulterathe compound. tion in

First find the specific gravity of the com-metals. pound, by weighing it in air and in water, and dividing its aerial weight by what it loses thereof in water, the quotient will shew its specific gravity,

gravity, or how many times it is heavier than its bulk of water. Then, fubtract the fpecific gravity of filver (found in the table) from that of the compound, and the fpecific gravity of the compound from that of gold; the first remaineder shews the bulk of gold, and the latter the bulk of filver, in the whole compound: and if these remainders be multiplied by the respective specific gravities, the products will shew the proportion of weights of each metal in the body. Example.

Suppose the specific gravity of the compounded body be 13; that of standard filver, (by the table) is 10.5, and that of gold 19.63: therefore 10.5 from 13, remains 2.5, the proportional bulk of the gold; and 13 from 19.63, remains 6.63 the proportional bulk of filver in the compound. Then, the first remainder 2.5, multiplied by 19.63, the specific gravity of gold, produces 49.075 for the proportional weight of gold; and the last remainder 6.63 multiplied by 10.5, the specific gravity of filver produces 69.615 for the proportional weight of filver in the whole body. So that for every 49.07 ounces or pounds of gold, there are 69.6 pounds or ounces of filver in the body.

Hence it is eafy to know whether any fufpected metal be genuine,, or allayed, or counterfeit; by finding how much it is heavier than its bulk of water, and comparing the fame with the table: if they agree, the metal is good; if they differ, it is allayed or counterfeited.

How to try spirituous liquors.

3

A cubical inch of good brandy, rum, or other proof fpirits, weighs 235.7 grains: therefore, if a true inch cube of any metal weighs 235.7 grains lefs in fpirits than in air, it fhews the fpirits are proof. If it lofes lefs of its aerial weight

weight in fpirits, they are above proof; if it lofes more, they are under. For, the better the fpirits are, they are the lighter; and the worfe, the heavier. All bodies expand with heat and contract with cold, but fome more and fome lefs than others. And therefore the specific gravities of bodies are not precifely the fame in fummer as in winter. It has been found, that a cubic inch of good brandy is ten grains heavier in winter than in fummer; as much spirit of nitre, 20 grains; vinegar 6 grains, and fpring-water 3. Hence it is most profitable to buy spirits in winter, and fell them in fummer, fince they are always bought and fold by meafure. It has been found, that 32 gallons of spirits in winter will make 33 in fummer.

The expansion of all fluids is proportionable to the degree of heat; that is, with a double or triple heat a fluid will expand two or three times as much.

Upon these principles depends the confiruc- The thertion of the thermometer, in which the globe or mometer. bulb, and part of the tube, are filled with a fluid, which, when joined to the barometer, is fpirits of wine tinged, that it may be more eafily feen in the tube. But when thermometers are made by themselves, quickfilver is generally used.

In the thermometer, a feale is fitted to the tube, to fhew the expansion of the quickfilver, and confequently the degree of heat. And, as *Fahrenheit*'s feale is most in effeem at prefent, I fhall explain the construction and graduation of thermometers according to that feale,

First, Let the globe or bulb, and part of the tube, be filled with a fluid; then immerse the bulb in water just freezing, or show just thawing;

ing; and even with that part in the feale where the fluid then flands in the tube, place the number 32, to denote the freezing point: then put the bulb under your arm-pit, when your body is of a moderate degree of heat, fo that it may acquire the fame degree of heat with your fkin; and when the fluid has rifen as far as it can by that heat, there place the number 97: then divide the fpace between thefe numbers into 65 equal parts, and continue those divisions both above 97 and below 32, and number them accordingly.

This may be done in any part of the world; for it is found that the freezing point is always the fame in all places, and the heat of the human body differs but very little; fo that the thermometers made in this manner will agree with one another; and the heat of feveral bodics will be fhewn by them, and expressed by the numbers upon the fcale, thus.

Air, in fevere cold weather, in our climate, from 15 to 25. Air in winter, from 26 to 42. Air in fpring and autumn, from 43 to 53. Air at midfummer, from 65 to 68. Extreme heat of the fummer fun, from 86 to 100. Butter just melting, 95. Alcohol boils with 174 or 175. Brandy with 190. Water 212. Oil of turpentine 550. Tin melts with 408, and lead with 540. Milk freezes about 30, vinegar 38, and blood 27.

A body fpecifically lighter than a fluid will fwim upon its furface, in fuch a manner, that a quantity of the fluid equal in bulk with the immerfed part of the body, will be as heavy as the whole body. Hence, the lighter a fluid is, the deeper a body will fink in it; upon which depends

depends the construction of the bydrometer or water-poife.

From this we can eafily find the weight of a How the thip, or any other body that floats in water, weight of For, if we multiply the number of cubic feet a thip which are under the furface, by 62.5, the number estimated. of pounds in one cubic foot of fresh water; or by 64.4, the number of pounds in a cubic foot of falt water; the product will be the weight of the fhip, and all that is in it. For, fince it is the weight of the fhip that difplaces the water, it must continue to fink until it has removed as much water as is equal to it in weight; and therefore the part immerfed must be equal in bulk to fuch a portion of the water as is equal to the weight of the whole fhip.

To prove this by experiment, let a ball of fome light wood, fuch as fir or pear-tree, be put into water contained in a glafs veffel; and let the veffel be put into a scale at one end of a balance, and counterpoifed by weights in the opposite scale: then, marking the height of the water in the vefiel, take out the ball; and fill up the veffel with water to the fame height that it flood at when the ball was in it; and the fame weight will counterpoife it as before.

From the veffel's being filled up to the fame height at which the water flood when the ball was in it, it is evident that the quantity poured in is equal in magnitude to the immerfed part of the ball; and from the fame weight counterpoifing, it is plain that the water poured in, is equal in weight to the whole ball.

In troy weight, 24 grains make a pennyweight, 20 pennyweights make an ounce, and 12 ounces a pound. In avoirdupoife weight, 16 drams make an ounce, and 16 ounces a M pound.

pound. The troy pound contains 5760 grains, and the avoirdupoife pound 7000; and hence, the avoirdupoife dram weighs 27.34375 grains, and the avoirdupoife ounce 437.5.

Because it is often of use to know how much any given quantity of goods in troy weight do make in avoirdupoife weight, and the reverfe; we shall here annex two tables for converting these weights into one another. Those from page 135 to page 146 are near enough for common hydraulic purpofes; but the two following are better, where accuracy is required in comparing the weights with one another : and I find, by trial, that 175 troy ounces are precifely equal to 192 avoirdupoife ounces, and 175 troy pounds are equal to 144 avoirdupoife. And although there are feveral leffer integral numbers, which come very near to agree together, yet I have found none lefs than the above to agree exactly. Indeed 41 troy ounces are fo nearly equal to 45 avoirdupoife ounces, that the latter contains only, 72 grains more than the former : and 45 troy pounds weigh only 73 drams more than 37 avoirdupoife.

I have lately made a fcale for comparing thefe weights with one another, and fhewing the weight of pump-water, proof fpirits, pure fpirits, and guinea gold, taken in cubic inches, to any quantity lefs than a pound, both in troy and avoirdupoife; only by fliding one fide of a fquare along the icale, and the other fide croffing it.

LECT. VI.

Of Pneumatics.

HIS fcience treats of the nature, weight, preffure, and fpring of the air, and the effects ariling therefrom.

The proair.

The air is that thin transparent fluid body in perties of which we live and breathe. It encompasses the whole earth to a confiderable height; and, together with the clouds and vapours that float in it, it is called the atmosphere. The air is justly reckoned among the number of fluids, becaufe it has all the properties by which a fluid is diftinguished. For, it yields to the least force imprefied, its parts are eafily moved among one another, it preffes according to its perpendicular height, and its preffure is every way equal.

> That the air is a fluid, confifting of fuch particles as have no cohefion betwixt them, but eafily glide over one another, and yield to the flightest impression, appears from that ease and freedom with which animals breathe in it, and move through it without any difficulty or fenfible refiftance.

> But it differs from all other fluids in the four following particulars. 1. It can be compreffed into a much lefs fpace than what it naturally poffeffeth, which no other fluid can. 2. It cannot be congealed or fixed, as other fluids may. g. It is of a different denfity in every part, upward from the earth's furface, decreasing in its weight, bulk for bulk, the higher it rifes; and therefore must also decrease in density. 4. It is of an elaftic

elaftic or fpringy nature, and the force of its fpring is equal to its weight.

That air is a body, is evident from its excluding all other bodies out of the fpace it poffeffes: for, if a glafs jar be plunged with its mouth downward into a veffel of water, there will but very little water get into the jar, becaufe the air of which it is full keeps the water out.

As air is a body, it muft needs have gravity or weight: and that it is weighty, is demonfirated by experiment. For, let the air be taken out of a veffel by means of the air-pump, then, having weighed the veffel, let in the air again, and upon weighing it when re-filled with air, it will be found confiderably heavier. Thus, a bottle that holds a wine quart, being emptied of air and weighed, is found to be about 16 grains lighter than when the air is let into it again ; which fhews that a quart of air weighs 16 grains. But a quart of water weighs 14021 grains; this divided by 16, quotes 914 in round numbers; which fhews, that water is 914 times as heavy as air near the furface of the earth.

As the air rifes above the earth's furface, it grows rarer, and confequently lighter, bulk for bulk. For, becaufe it is of an elaftic or fpringy nature, and its lowermost parts are prefied with the weight of all that is above them, it is plain that the air must be more dense or compact at the earth's furface, than at any height above it; and gradually rarer the higher up. For, the density of the air is always as the force that compressed it; and therefore, the air towards the upper parts of the atmosphere being lefs pressed than that which is near the earth, it will expand itself, and thereby become thinner than at the earth's furface.

Dr.

Dr. Cotes has demonstrated, that if altitudes in the air be taken in arithmetical proportion, the rarity of the air will be in geometrical proportion. For instance,

And hence it is eafy to prove by calculation, that a cubic inch of fuch air as we breathe, would be fo much rarefied at the altitude of 500 miles, that it would fill a hollow fphere equal in diameter to the orbit of Saturn.

The weight or preffure of the air is exactly determined by the following experiment.

The Toricellian experiment. Take a glass tube about three feet long, and open at one end; fill it with quickfilver, and putting your finger upon the open end, turn that end downward, and immerfe it into a fmall veffel

veffel of quickfilver, without letting in any air : then take away your finger; and the quickfilver will remain fuspended in the tube 29th inches above its furface in the veffel; fometimes more, and at other times lefs, as the weight of the air is varied by winds and other caufes. That the quickfilver is kept up in the tube by the preffure of the atmosphere upon that in the bafon, is evident; for, if the bason and tube be put under a glafs, and the air be then taken out of the glafs, all the quickfilver in the tube will fall down into the bafon; and if the air be let in again, the quickfilver will rife to the fame height as before. Therefore the air's preffure on the furface of the earth, is equal to the weight of 29¹/₂ inches depth of quickfilver all over the earth's furface, at a mean rate.

A fquare column of quickfilver, 29¹/₂ inches high, and one inch thick, weighs juft 15 pounds, which is equal to the preffure of air upon every square inch of the earth's surface; and 144 times as much, or 2160 pounds, upon every square foot; because a square foot contains 144 fquare inches. At this rate, a middlefized man, whole furface may be about 14 fquare feet, fustains a preffure of 30240 pounds, when the air is of a mean gravity : a preffure which would be infupportable, and even fatal to us, were it not equal on every part, and counterbalanced by the fpring of the air within us, which is diffufed through the whole body; and re-acts with an equal force against the outward preffure.

Now, fince the earth's furface contains (in round numbers) 200,000,000 fquare miles, and every fquare mile 27,878,400 fquare feet, there must be 5,575,680,000,000,000 fquare feet
feet on the earth's furface; which multiplied by 2160 pounds (the preffure on each fquare foot) gives 12,043,468,800,000,000,000 pounds for the preffure or weight of the whole atmofphere.

When the end of a pipe is immerfed in water, and the air is taken out of the pipe, the water will rife in it to the height of 33 feet above the furface of the water in which it is immerfed : but will go no higher: for it is found, that a common pump will draw water no higher than 33 feet above the furface of the well: and unleis the bucket goes within that diffance from the well, the water will never get above it. Now, as it is the preffure of the atmosphere, on the furface of the water in the well, that caufes the water to afcend in the pump, and follow the pifton or bucket, when the air above it is lifted up; it is evident, that a column of water 33 feet high, is equal in weight to a column of quickfilver of the fame diameter, 291 inches high; and to as thick a column of air, reaching from the earth's furface to the top of the atmolphere.

The barometer. In ferene calm weather, the air has weight enough to fupport a column of quickfilver 31 inches high; but in tempeftuous flormy weather, not above 28 inches. The quickfilver, thus fupported in a glafs tube, is found to be a nice counterbalance to the weight or preffure of the air, and to fhew its alterations at different times. And being now generally ufed to denote the changes in the weight of the air, and of the weather confequent upon them, it is called the *barometer*, or weather-glafs.

The preffure of the air being equal on all fides of a body exposed to it, the foftest bodies fustain

fultain this preffure without fuffering any change in their figure; and fo do the most brittle bodies without being broke.

The air is rarefied, or made to fwell with heat ; and of this property, wind is a necessary The cause confequence. For, when any part of the air is of winds. heated by the fun, or otherwife, it will fwell, and thereby affect the adjacent air : and fo, by various degrees of heat in different places, there will arife various winds.

When the air is much heated, it will afcend towards the upper part of the atmosphere, and the adjacent air will rush in to supply its place; and therefore, there will be a fiream or current of air from all parts towards the place where the heat is. And hence we fee the reafon why the air rufhes with fuch force into a glafs-houfe, or towards any place where a great fire is made. And alfo, why fmoke is carried up a chimney, and why the air rushes in at the key-hole of the door, or any fmall chink, when there is a fire in the room. So we may take it in general, that the air will prefs towards that part of the world where it is most heated.

Upon this principle, we can eafily account for The the trade-winds, which blow constantly from east tradeto weft about the equator. For, when the fun winds. fhines perpendicularly on any part of the earth, it will heat the air very much in that part, which air will therefore rife upward, and when the fun withdraws, the adjacent air will rush in to fill its place; and confequently will caufe a ftream or current of air from all parts towards that which is most heated by the fun. But as the fun, with respect to the earth, moves from east to west, the common course of the air will be that way too; continually preffing after the fun: and therefore.

therefore, at the equator, where the fun fhines ftrongly, there will be a continual wind from the eaft; but, on the north fide, it will incline a little to the north, and on the fouth-fide, to the fouth.

This general course of the wind about the equator, is changed in feveral places, and upon feveral accounts; as, I. By exhalations that rife out of the earth at certain times, and from certain places; in earthquakes, and from volcanos. 2. By the falling of great quantities of rain, caufing thereby a fudden condenfation or contraction of the air. 3. By burning fands, that often retain the folar heat to a degree incredible to those who have not felt it, caufing a more than ordinary rarefaction of the air contiguous to them. 4. By high mountains, which alter the direction of the winds in striking against them. 5. By the declination of the fun towards the north or fouth, heating the air on the north or fouth fide of the equator.

The monfoons.

To thefe and fuch like caufes is owing, 1. The irregularity and uncertainty of winds in climates diftant from the equator, as in most parts of *Europe.* 2. Those periodical winds, called *monfoons*, which in the *Indian* feas blow half a year one way, and the other half another. 3. Those winds which, on the coast of *Guiney*, and on the western coasts of *America*, blow always from west to east. 4. The fea-breezes, which, in hot countries, blow generally from fea to land, in the day-time; and the landbreezes, which blow in the night; and, in fhort, all those florms, hurricanes, whirlwinds, and irregularities, which happen at different times and places.

All

All common air is impregnated with a cer. The vivitain kind of vivifying fpirit or quality, which is fying fpineceffary to continue the lives of animals : and rit in air. this, in a gallon of air, is fufficient for one man during the fpace of a minute, and not much longer.

This fpirit in air is deftroyed by paffing through the lungs of animals: and hence it is, that an animal dies foon, after being put under a veffel which admits no frefh air to come to it. This fpirit is alfo in the air which is in water; for fifh die when they are excluded from frefh air, as in a pond that is clofely frozen over. And the little eggs of infects, ftopped up in a glafs, do not produce their young, though affifted by a kindly warmth. The feeds alfo of plants mixed with good earth, and inclofed in a glafs, will not grow.

This enlivening quality in air, is alfo deftroyed by the air's paffing through fire; particularly charcoal fire, or the flame of fulphur. Hence, fmoking chimneys must be very unwholefome, especially if the rooms they are in be fmall and close.

Air is alfo vitiated, by remaining clofely pent up in any place for a confiderable time; or perhaps, by being mixed with malignant fteams and particles flowing from the neighbouring bodies : or laftly, by the corruption of the vivifying fpirit; as in the holds of fhips, in oil-cifterns, or wine-cellars, which have been fhut for a confiderable time. The air in any of them is fometimes fo much vitiated, as to be immediate death to any animal that comes into it.

Air that has loft its vivifying fpirit, is called Damps. damp, not only becaufe it is filled with humid or moift vapours, but becaufe it deadens fire, extin-

extinguishes flame, and deftroys life. The dreadful effects of damps are fufficiently known to fuch as work in mines.

If part of the vivifying fpirit of air in any country begins to putrefy, the inhabitants of that country will be fubject to an epidemical difeafe, which will continue until the putrefaction is over. And as the putrefying fpirit occasions the difeafe, fo if the difeafed body contributes towards the putrefying of the air, then the difeafe will not only be epidemical, but pestilential and contagious.

The atmosphere is the common receptacle of all the effluvia or vapours arising from different bodies; of the fteams and smoke of things burnt or melted; the fogs or vapours proceeding from damp watery places; and of the effluvia from fulphureous, nitrous, acid, and alkaline bodies. In short, whatever may be called volatile, rifes in the air to greater or less heights, according to its specific gravity.

Fermentations,

When the effluvia, which arife from acid and alkaline bodies, meet each other in the air, there will be a ftrong conflict or *fermentation* between them; which will fometimes be fo great, as to produce a fire; then if the effluvia be combuftible, the fire will run from one part to another, just as the inflammable matter happens to lie.

Any one may be convinced of this, by mixing an acid and an alkaline fluid together, as the fpirit of nitre and oil of cloves; upon the doing of which, a fudden ferment, with a fine flame, will arife; and if the ingredients be very pure and ftrong, there will be a fudden explosion.

Thunder Whoever confiders the effects of fermentaand light-tion, cannot be at a loss to account for the ning. dreadful

dreadful effects of *thunder* and *lightning*: for the effluvia of fulphureous and nitrous bodies, and others that may rife into the atmosphere, will ferment with each other, and take fire very often of themselves; fometimes by the affiftance of the fun's heat.

If the inflammable matter be thin and light, it will rife to the upper part of the atmosphere, where it will flash without doing any harm: but if it be denfe, it will lie near the furface of the earth, where taking fire, it will explode with a furprifing force; and by its heat rarefy and drive away the air, kill men and cattle, fplit trees, walls, rocks, &c. and be accompanied with terrible claps of thunder.

The heat of lightning appears to be quite different from that of other fires; for it has been known to run through wood, leather, cloth, &c. without hurting them, while it has broken and melted iron, fteel, filver, gold, and other hard bodies. Thus it has melted or burnt afunder a fword, without hurting the fcabbard; and money in a man's pocket, without hurting his cloaths: the reafon of this feems to be, that the particles of *that* fire are fo fine, as to pafs through foft loofe bodies without diffolving them; whilft they fpend their whole force upon the hard ones.

It is remarkable, that knives and forks which have been flruck with lightning have a very flrong magnetical virtue for feveral years after; and I have heard that lightning flriking upon the mariner's compais, will fometimes turn it round; and often make it fland the contrary way; or with the north-pole towards the fouth.

Much of the fame kind with lightning, are Firethose explosions, called *fulminating* or *fire-damps*, *damps*.

which fometimes happen in mines; and are occafioned by fulphureous and nitrous, or rather oleaginous particles, rifing from the mine, and mixing with the air, where they will take fire by the lights which the workmen are obliged to make use of. The fire being kindled will run from one part of the mine to another, like a train of gunpowder, as the combustible matter happens to lie. And as the elafticity of the air is increafed by heat, that in the mine will confequently fwell very much, and fo, for want of room, will explode with a greater or lefs degree of force, according to the denfity of the combuftible vapours. It is fometimes fo ftrong, as to blow up the mine; and at other times fo weak, that when it has taken fire at the flame of a candle, it is eafily blown out.

Air that will take fire at the flame of a candle may be produced thus. Having exhaufted a receiver of the air-pump, let the air run into it through the flame of the oil of turpentine; then remove the cover of the receiver, and holding a candle to that air, it will take fire, and burn quicker or flower, according to the denfity of the oleaginous vapour.

Earthquakes. When fuch combustible matter, as is abovementioned, kindles in the bowels of the earth, where there is little or no vent, it produces *earthquakes*, and violent florms or hurricanes of wind when it breaks forth into the air.

An artificial earthquake may be made thus. Take 10 or 15 pounds of fulphur, and as much of the filings of iron, and knead them with common water into the confiftency of a pafte : this being buried in the ground, will, in 8 or 10 hours time, buft out in flames, and caufe the

PLATE XIV.

J. Mynde foulp

the earth to tremble all around to a confiderable diftance.

From this experiment we have a very natural account of the fires of mount *Ætna*, *Vefuvius*, and other volcanos, they being probably fet or fire at first by the mixture of fuch metalline and fulphureous particles.

The air pump being conftructed the fame way PlateXIV. as the water-pump, whoever underftands the Fig. 1. one, will be at no lofs to underftand the other.

Having put a wet leather on the plate LL The airof the air-pump, place the glass receiver Mpump. upon the leather, fo that the hole i in the plate may be within the glafs. Then, turning the handle F backward and forward, the air will be pumped out of the receiver; which will then be held down to the plate by the preffure of the external air, or atmosphere. For, as the handle F(Fig. 2.) is turned backwards, it raifes the pifton de in the barrel BK, by means of the wheel E and rack Dd: and, as the pifton is leathered fo tight as to fit the barrel exactly, no air can get between the pifton and barrel; and therefore, all the air above d in the barrel is lifted up towards B, and a vacuum is made in the barrel from b to e; upon which, part of the air in the receiver M (Fig. 1.) by its fpring, rushes through the hole i, in the brass plate LL, along the pipe GCG (which communicates with both barrels by the hollow trunk IHK (Fig. 2.) and puffing up the valve b, enters into the vacant place be of the barrel BK. For, wherever the refiftance or preffure is taken off, the air will run to that place, if it can find a paffage .- Then, if the handle F be turned forward, the pifton de will be depressed in the barrel; and, as the air which had got into the N barrel

harrel cannot be puffed back through the valve b, it will afcend through a hole in the pifton, and escape through a valve at d; and be hindered by that valve from returning into the barrel, when the pifton is again raifed. At the next raifing of the pifton, a vacuum is again made in the fame manner as before, between b and e; upon which, more of the air that was left in the receiver M, gets out thence by its fpring, and runs into the barrel B K, through the valve B. The fame thing is to be underftood with regard to the other barrel AI; and as the handle F is turned backwards and forwards, it alternately raifes and depreffes the piftons in their barrels; always raifing one whilft it depresses the other. And, as there is a vacuum made in each barrel when its pifton is raifed, the particles of air in the receiver M push out another by their spring or elasticity, through the hole i_{i} and pipe GG into the barrels; until at laft the air in the receiver comes to be fo much dilated, and its fpring fo far weakened, that it can no longer get through the valves; and then no more can be taken out. Hence, there is no fuch thing as making a perfect vacuum in the receiver; for the quantity of air taken out at any one ftroke, will always be as the denfity thereof in the receiver : and therefore it is impoffible to take it all out, becaufe, fuppoling the receiver and barrels of equal capacity, there will be always as much left as was taken out at the last turn of the handle.

There is a cock k below the pump-plate, which being turned, lets the air into the receiver again; and then the receiver becomes loofe, and may be taken off the plate. The barrels are fixed to the frame E e e by two forew-nuts ff, which

which prefs down the top piece E upon the barrels: and the hollow trunk H (in Fig. 2.) is covered by a box, as G H in Fig. 1.

There is a glass tube Immmn open at both ends, and about 34 inches long; the upper end communicating with the hole in the pump-plate, and the lower end immerfed in quickfilver at n in the veffel N. To this tube is fitted a wooden ruler m m, called the gage, which is divided into inches and parts of an inch, from the bottom at n (where it is even with the furface of the quickfilver) and continued up to the top, a little below l, to 30 or 31 inches.

As the air is pumped out of the receiver M, it is likewife pumped out of the glafs tube lmn, becaufe that tube opens into the receiver through the pump-plate; and as the tube is gradually emptied of air, the quckfilver in the veffel N is forced up into the tube by the preffure of the atmosphere. And if the receiver could be perfectly exhaufted of air, the quickfilver would ftand as high in the tube as it does at that time in the barometer : for it is supported by the fame power or weight of the atmosphere in both.

The quantity of air exhaufted out of the receiver on each turn of the handle, is always proportionable to the afcent of the quickfilver on that turn; and the quantity of air remaining in the receiver, is proportionable to the defect of the height of the quickfilver in the gage, from what it is at that time in the barometer.

I shall now give an account of the experiments made with the air-pump in my lectures; fnewing the refiftance, weight, and elafticity of the air. the to appropriate Los N 2 20 gaived Los

I. To

I. To frew the refiftance of the air.

Fig. 3.

1. There is a little machine, confifting of two mills, a and b, which are of equal weights, independent of each other, and turn equally free on their axes in the frame. Each mill has four thin arms or fails, fixed into the axis : those of the mill a have their planes at right angles to its axis, and those of b have their planes parallel to Therefore, as the mill a turns round in comit. mon air, it is but little refifted thereby, becaufe it's fails cut the air with their thin edges: but the mill b is much refifted, becaufe the broad fides of it's fails move against the air when it turns round. In each axle is a pin near the middle of the frame, which goes quite through. the axle, and flands out a little on each fide of it: upon these pins, the flider d may be made to bear, and fo hinder the mills from going, when the ftrong fpring c is fet on bend against the opposite ends of the pins.

Having let this machine upon the pumpplate L L (Fig. 1.) draw up the flider d to the pins on one fide, and fet the fpring c at bend upon the opposite ends of the pins: then push down the flider d, and the fpring acting equally ftrong upon each mill, will fet them both a going with equal forces and velocities: but the mill awill run much longer than the mill b, because the air makes much lefs refiftance against the edges of its fails, than against the fides of the fails of b.

Draw up the flider again, and fet the fpring upon the pins as before; then cover the machine with the receiver M upon the pumpplate, and having exhausted the receiver of air, push

Fig. 1.

push down the wire PP (through the coller of leathers in the neck q) upon the flider; which will difengage it from the pins, and allow the mills to turn round by the impulse of the fpring; and as there is no air in the receiver to make any fenfible refiftance against them, they will both move a confiderable time longer than they did in the open air; and the moment that one flops, the other will do fo too .- This fnews that air refifts bodies in motion, and that equal bodies meet with different degrees of refiftance, according as they prefent greater or lefs furfaces to the air, in the planes of their motions.

2. Take off the receiver M, and the mills ; Fig. 4. and having put the guinea a and feather b upon the brafs flap c, turn up the flap, and fhut it into the notch d. Then, putting a wet leather over the top of the tall receiver AB(it being open both at top and battom) cover it with the plate C, from which the guinea and feather tongs ed will then hang within the receiver. This done, pump the air out of the receiver; and then draw up the wire f a little, which by a fquare piece on its lower end will open the tongs ed; and the flap falling down as at c, the guinea and feather will defcend with equal velocities in the receiver : and both will fall upon the pump-plate at the fame inftant. N. B. In this experiment, the observers ought not to look at the top, but at the bottom of the receiver; in order to fee the guinea and feather fall upon the plate: otherwife, on account of the quickness of their motion, they will escape the fight of the beholders.

N 3 II. To

II. To shew the weight of the air.

1. Having fitted a brafs cap, with a valve tied over it, to the mouth of a thin bottle or Florence flafk, whofe contents are exactly known, fcrew the neck of this cap into the hole i of the pump-plate: then, having exhausted the air out of the flafk, and taken it off from the pump, let it be fuspended at one end of a balance, and nicely counterpoifed by weights in the fcale at the other end : this done, raife up the valve with a pin, and the air will rush into the flask with an audible noife : during which time, the flafk will defcend. and pull down that end of the beam. When the noife is over, put as many grains into the fcale at the other end as will reftore the equilibrium; and they will fnew exactly the weight of the quantity of air which has got into the flafk, and filled it. If the flask holds an exact quart, it will be found, that 16 grains will reftore the equipoife of the balance, when the quickfilver ftands at 292 inches in the barometer: which fhews, that when the air is at a mean rate of denfity, a quart of it weighs 16 grains : it weighs more when the quickfilver ftands higher; and lefs when it ftands lower.

2. Place the finall receiver O (Fig. 1.) over the hole *i* in the pump-plate, and upon exhaufting the air, the receiver will be fixed down to the plate by the prefiure of the air on its outfide, which is left to act alone, without any air in the receiver to act against it: and this prefiure will be equal to as many times 15 pounds, as there are fquare inches in that part of the plate which the receiver covers; which will hold down the receiver to faft, that it cannot be got off, until

5

the air be let into it by turning the cock k; and then it becomes loofe.

3. Set the little glafs \mathcal{A} B (which is open at Fig. 5. both ends) over the hole *i* upon the pump-plate L L, and put your hand close upon the top of it at B: then, upon exhausting the air out of the glafs, you will find your hand preffed down with a great weight upon it: fo that you can hardly release it, until the air be re-admitted into the glafs by turning the cock k; which air, by acting as strongly upward against the hand as the external air acted in prefing it downward, will release the hand from its confinement.

4. Having tied a piece of wet bladder b over Fig. 6. the open top of the glafs A (which is also open at bottom) fet it to dry, and then the bladder will be tight like a drum. Then place the open end A upon the pump-plate, over the hole i, and begin to exhauft the air out of the glafs. As the air is exhaufting, its fpring in the glafs will be weakened, and give way to the preffure of the outward air on the bladder, which, as it is preffed down, will put on a fpherical concave figure, which will grow deeper and deeper, until the ftrength of the bladder be overcome by the weight of the air; and then it will break with a report as loud as that of a gun .- If a flat piece of glass be laid upon the open top of this receiver, and joined to it by a flat ring of wet leather between them; upon pumping the air out of the receiver, the preffure of the outward air upon the flat glafs will break it all to pieces.

5. Immerfe the neck c d of the hollow glafs Fig: 7: ball eb in water, contained in the phial aa; then fet it upon the pump-plate, and cover it and the hole *i* with the clofe receiver A; and then begin N 4 to

to pump out the air. As the air goes out of the receiver by its fpring, it will also by the fame means go out of the hollow ball eb, through the neck dc, and rife up in bubbles to the furface of the water in the phial; from whence it will make its way, with the reft of the air in the receiver, through the air-pipe GG and valves a and b, into the open air. When it has done bubbling in the phial, the ball is fufficiently exhausted; and then, upon turning the cock k, the air will get into the receiver, and prefs fo upon the furface of the water in the phial, as to force the water up into the ball in a jet, through the neck cd; and will fill the ball almost full of water. The reafon why the ball is not quite filled, is becaufe all the air could not be taken out of it; and the fmall quantity that was left in, and had expanded itfelf fo as to fill the whole ball, is now condenfed into the fame state as the outward air, and remains in a small bubble at the top of the ball; and fo keeps the water from filling that part of the ball.

Fig. S.

6. Pour fome quickfilver into the jar D, and fet it on the pump-plate near the hole i; then fet on the tall open receiver AB, fo as to be over the jar and hole; and cover the receiver with the brass plate C. Screw the open glass tube fg(which has a brafs top on it at b) into the fyringe H, and putting the tube through a hole in the middle of the plate, fo as to immerfe the lower end of the tube e in the quickfilver at D, ferew the end b of the fyringe into the plate. This done, draw up the pifton in the fyringe by the ring I, which will make a vacuum in the fyringe, below the pifton; and as the upper end of the tube opens into the fyringe, the air will be dilated in the tube, because part of it, by its fpring, gets

gets up into the fyringe; and the fpring of the un-dilated air in the receiver acting upon the furface of the quickfilver in the jar, will force part of it up into the tube : for the quickfilver will follow the pifton in the fyringe, in the fame way, and for the fame reafon, that water follows the pifton of a common pump when it is raifed in the pump barrel; and this, according to fome, is done by fuction. But to refute that erroneous notion, let the air be pumped out of the receiver AB, and then all the quickfilver in the tube will fall down by its own weight into the jar; and cannot be again raifed one hair's breadth in the tube by working the fyringe: which fhews that fuction had no hand in raifing the quickfilver; and, to prove that it is done by preffure, let the air into the receiver by the cock k (Fig. 1.) and its action upon the furface of the quickfilver in the Jar will raife it up into the tube, although the pifton of the fyringe continues motionlefs .- If the tube be about 32 or 33 inches high, the quickfilver will rife in it very near as high as it ftands at that time in the barometer. And, if the fyringe has a fmall hole, as m, near the top of it, and the pifton be drawn up above that hole, the air will rufh through the hole into the fyringe and tube, and the quickfilver will immediately fall down into the jar. If this part of the apparatus be air-tight, the quickfilver may be pumped up into the tube to the fame height that it ftands in the barometer; but it will go no higher, because then the weight of the column in the tube is the fame as the weight of a column of air of the fame thickness with the quickfilver, and reaching from the earth to the top of the atmosphere.

7. Having

Fig. 9.

7. Having placed the jar A, with fome quickfilver in it, on the pump-plate, as in the laft experiment, cover it with the receiver B; then push the open end of the glass tube de through the collar of leathers in the brafs neck C (which it fits fo as to be air-tight) almost down to the quickfilver in the jar. Then exhauft the air out of the receiver, and it will also come out of the tube, becaufe the tube is close at top. When the gauge mm fhews that the receiver is well exhaufted, pulh down the tube, fo as to immerfe. its lower end into the quickfilver in the jar. Now, although the tube be exhausted of air. none of the quickfilver will rife into it, becaufe there is no air left in the receiver to prefs upon its furface in the jar. But let the air into the receiver by the cock k, and the quickfilver will immediately rife in the tube; and ftand as high in it, as it was pumped up in the laft experiment.

Both these experiments flew, that the quickfilver is supported in the barometer by the preffure of the air on its furface in the box, in which the open end of the tube is placed. And that the more denfe and heavy the air is, the higher does the quickfilver rife; and, on the contrary, the thinner and lighter the air is, the more will the quickfilver fall. For if the handle F be turned ever fo little, it takes fome air out of the receiver, by raifing one or other of the piftons in its barrel; and confequently, that which remains in the receiver is fo much the rarer, and has to much the lefs fpring and weight; and thereupon, the quickfilver falls a little in the tube : but upon turning the cock, and re-admitting the air into the receiver, it becomes as weighty as before, and the quickfilver rifes again to the fame height.

height.— Thus we fee the reafon why the quickfilver in the barometer falls before rain or fnow, and rifes before fair weather; for, in the former cafe, the air is too thin and light to bear up the vapours, and in the latter, too denfe and heavy to ler them fall.

N. B. In all mercurial experiments with the air-pump, a fhort pipe must be forewed into the hole i, fo as to rife about an inch above the plate, to prevent the quickfilver from getting into the air-pipe and barrels, in cafe any of it fhould be accidentally fpilt over the jar: for if it once gets into the pipes or barrels, it fpoils them, by loofening the folder, and corroding the brafs.

8. Take the tube out of the receiver, and put one end of a bit of dry hazel branch, about an inch long, tight into the hole, and the other end tight into a hole quite through the bottom of a fmall wooden cup : then pour fome quickfilver into the cup, and exhauft the receiver of air, and the preffure of the outward air, on the furface of the quickfilver, will force it through the pores of the hazel, from whence it will defcend in a beautiful fhower into a glass cup placed under the receiver to catch it.

9. Put a wire through the collar of leathers in the top of the receiver, and fix a bit of dry wood on the end of the wire within the receiver; then exhauft the air, and puft the wire down, fo as to immerfe the wood into a jar of quickfilver on the pump-plate; this done, let in the air, and upon taking the wood out of the jar, and fplitting it, its pores will be found full of quickfilver, which the force of the air, upon being let into the receiver, drove into the wood.

10. Join the two brass hemispherical cups A and Fig. 10. B together, with a wet leather between them, hay-

ing

ing a hole in the middle of it; then forew the end D of the pipe C D into the plate of the pump at i, and turn the cock E, fo as the pipe may be open all the way into the cavity of the hemispheres : then exhaust the air out of them, and turn the cock a quarter round, which will fhut the pipe CD, and keep out the air. This done, unferew the pipe at D from the pump; and icrew the piece Fb upon it at D; and let two firong men try to pull the hemispheres afunder by the rings g and b, which they will find hard to do: for if the diameter of the hemifpheres be four inches, they will be preffed together by the external air with a force equal to 190 pounds. And to fhew that it is the preffure of the air that keeps them together, hang them by either of the rings upon the hook P of the wire in the receiver M (Fig. 1.) and upon exhaufting the air out of the receiver, they will fall afunder of themfelves.

11. Place a small receiver O (Fig. 1.) near the hole i on the pump-plate, and cover both it and the hole with the receiver M; and turn the wire fo by the top P, that its hook may take hold of the little receiver by a ring at its top, allowing that receiver to ftand with its own weight on the plate. Then, upon working the pump, the air will come out of both receivers ; but the large one M will be forcibly held down to the pump by the preffure of the external air; whilft the fmall one O, having no air to prefs upon it, will continue loofe, and may be drawn up and let down at pleafure, by the wire P P. But, upon letting it quite down to the plate, and admitting the air into the receiver M, by the cock k, the air will prefs fo ftrongly upon the fmall receiver O, as to fix it down to the plate; and at the

the fame time, by counterbalancing the outward preffure on the large receiver M, it will become loofe. This experiment evidently flews, that the receivers are held down by preffure, and not by fuction, for the internal receiver continued loofe whilf the operator was pumping, and the external one was held down; but the former became fast immediately by letting in the air upon it.

12. Screw the end A of the brafs pipe ABF Fig. 11. into the hole of the pump-plate, and turn the cock e until the pipe be open; then put a wet leather upon the plate cd, which is fixed on the pipe, and cover it with the tall receiver GH, which is close at top: then exhauft the air out of the receiver, and turn the cock e to keep it out; which done, unforew the pipe from the pump, and fet its end A into a bafon of water, and turn the cock e to open the pipe; on which, as there is no air in the receiver, the preffure of the atmosphere on the water in the bafon will drive the water forcibly through the pipe, and make it play up in a jet to the top of the receiver.

13. Set the fquare phial A (Fig. 14.) upon the pump-plate, and having covered it with the wire cage B, put a clofe receiver over it, and exhauft the air out of the receiver; in doing of which, the air will alfo make its way out of the phial through a fmall hole in its neck under the valve b. When the air is exhaufted, turn the cock below the plate, to re-admit the air into the receiver; and as it cannot get into the phial again, becaufe of the valve, the phial will be broke into fome thousands of pieces by the preffure of the air upon it. Had the phial been of a round form, it would have fuftained this preflure

preffure like an arch, without breaking; but as its fides are flat, it cannot.

To shew the elasticity or spring of the air.

14. Tie up a very fmall quantity of air in a bladder, and put it under a receiver; then exhauft the air out of the receiver; and the fmall quantity which is confined in the bladder (having nothing to act against it) will expand itself to by the force of its spring, as to fill the bladder as full as it could be blown of common air. But upon letting the air into the receiver again, it will overpower the air in the bladder, and prefs its fides almost close together.

15. If the bladder fo tied up be put into a wooden box, and have 20 or 30 pound weight of lead put upon it in the box, and the box be covered with a clofe receiver; upon exhaulting the air out of the receiver, that air which is confined in the bladder will expand itfelf fo, as to raife up all the lead by the force of its fpring.

Fig. 7.

16. Take the glafs ball mentioned in the fifth experiment, which was left full of water all but a fmall bubble of air at top, and having fet it with its neck downward into the empty phial *aa*, and covered it with a clofe receiver, exhauft the air out of the receiver, and the fmall bubble of air in the top of the ball will expand itfelf, fo as to force all the water out of the ball into the phial.

Fig. 11.

17. Screw the pipe AB into the pump-plate, place the tall receiver GH upon the plate cd, as in the twelfth experiment, and exhauft the air out of the receiver; then, turn the cock e to keep out the air, unforew the pipe from the pump, and forew it into the mouth of the copper veffel

veffel CC (Fig. 15.) the veffel having first been about half filled with water. Then open the cock e (Fig. 11.) and the fpring of the air which is confined in the copper veffel will force the water up through the pipe AB in a jet into the exhaufted receiver, as ftrongly as it did by its preffure on the furface of the water in a bason, in the twelfth experiment.

18. If a fowl, a cat, rat, moufe, or bird, be put under a receiver, and the air be exhaufted, the animal will be at first oppressed as with a great weight, then grow convulled, and at laft expire in all the agonies of a most bitter and cruel death. But as this experiment is too fhocking to every fpectator who has the leaft degree of humanity, we fubftitute a machine called the lungs-glass in place of the animal.

19. If a butterfly be fuspended in a receiver, by a fine thread tied to one of its horns, it will fly about in the receiver, as long as the receiver continues full of air; but if the air be exhaufted. though the animal will not die, and will continue to flutter its wings, it cannot remove itself from the place where it hangs in the middle of the receiver, until the air be let in again, and then the animal will fly about as before.

20. Pour fome quickfilver into the fmall bottle Fig. 12. A, and forew the brafs collar c of the tube BC into the brafs neck b of the bottle, and the lower end of the tube will be immerfed into the quickfilver, fo that the air above the quickfilver in the bottle will be confined there, becaufe it cannot get out about the joinings, nor can it be drawn out through the quickfilver into the tube. This tube is also open at top, and is to be covered with the receiver G and large tube E F, which tube is fixed by brafs collars to the receiver, and is clofe at

at the top. This preparation being made, exhauft the air both out of the receiver and its tube; and the air will by the fame means be exhaufted out of the inner tube BC, through its open top at C; and as the receiver and tubes are exhaufting, the air that is confined in the glass bottle A will prefs fo by its fpring upon the furface of the quickfilver, as to force it up in the inner tube as high as it was raifed in the ninth experiment by the preffure of the atmosphere: which demonsfrates that the firing of the air is equivalent to its weight.

Fig. 13.

21. Screw the end C of the pipe C D into the hole of the pump-plate, and turn all the three cocks d, G, and H, fo as to open the communications between all the three pipes E, F, DC, and the hollow trunk AB. Then, cover the plates g and b with wet leathers, which have holes in their middle where the pipes open into the plates; and place the clofe receiver I upon the plate g: this done, fhut the pipe F by turning the cock H, and exhauft the air out of the receiver I. Then, turn the cock d to fhut out the air, unferew the machine from the pump, and having fcrewed it to the wooden foot L, put the receiver K upon the plate b; this receiver will continue loofe on the plate as long as it keeps full of air; which it will do until the cock H be turned to open the communication between the pipes F and E, through the trunk AB; and then the air in the receiver K, having nothing to act against its spring, will run from K into I, until it be fo divided between thefe receivers, as to be of equal denfity in both; and then they will be held down with equal forces to their plates by the prefiure of the atmosphere; though each receiver will then be kept down but with one half

half of preffure upon it, that the receiver I had, when it was exhaulted of air; because it has now one half of the common air in it which filled the receiver K when it was fet upon the plate; and therefore, a force equal to half the force of the fpring of common air, will act within the receivers against the whole preffure of the common air upon their outfides. This is called transferring the air out of one veffel into another

22. Fut a cork into the square phial A, and Fig. 14. fix it in with wax or cement; put the phial upon the pump-plate with the wire cage B over it, and cover the cage with a close receiver. Then, exhauft the air out of the receiver, and the air that was corked up in the phial will break the phial outwards by the force of its fpring, becaufe there is no air left on the outfide of the phial to act against the air within it.

23. Put a shrivelled apple under a close receiver, and exhauft the air ; then the fpring of the air within the apple will plump it out, fo as to caufe all the wrinkles difappear; but upon letting the air into the receiver again, to prefs upon the apple, it will inftantly return to its former decayed and fhrivelled ftate.

24. Take a fresh egg, and cut off a little of the shell and film from its smallest end, then put the egg under a receiver, and pump out the air; upon which, all the contents in the egg will be forced out into the receiver, by the expansion of a fmall bubble of air contained in the great end, between the fhell and film.

25. Put fome warm beer into a glafs, and having fet it on the pump, cover it with a close receiver, and then exhauft the air. Whilft this is doing, and thereby the preffure more and more

taken

taken off from the beer in the glass, the air therein will expand itself, and rife up in innumerable bubbles to the furface of the beer; and from thence it will be taken away with the other air in the receiver. When the receiver is nearly exhausted, the air in the beer, which could not difentangle itself quick enough to get off with the reft, will now expand itself fo, as to cause the beer to have all the appearance of boiling; and the greatest part of it will go over the glass.

26. Put fome warm water into a glafs, and put a bit of dry wainfeet or other wood into the water. Then, cover the glafs with a clofe receiver, and exhauft the air; upon which, the air in the wood having liberty to expand itfelf, will come out plentifully, and make all the water to bubble about the wood, efpecially about the ends, becaufe the pores lie lengthwife. A cubic inch of dry wainfeet has fo much air in it, that it will continue bubbling for near half an hour together.

Miscellaneous Experiments.

27. Screw the fyringe H (Fig. 8.) to a piece of lead that weighs one pound at leaft; and, holding the lead in one hand, pull up the pifton in the fyringe with the other; then, quitting hold of the lead, the air will pufh it upward, and drive back the fyringe upon the pifton. The reafon of this is, that the drawing up of the pifton makes a vacuum in the fyringe, and the air, which preffes every way equally, having nothing to refift its preffure upward, the lead is thereby preffed upward, contrary to its natural tendency by gravity. If the fyringe, fo loaded, be

be hung in a receiver, and the air be exhaulted, the fyringe and lead will defcend upon the piftonrod by their natural gravity; and, upon admitting the air into the receiver, they will be drove upward again, until the pifton be at the very bottom of the fyringe.

28. Let a large piece of cork be fuspended by a thread at one end of a balance, and counterpoifed by a leaden weight, fuspended in the fame manner, at the other. Let this balance be hung to the infide of the top of a large receiver; which being fet on the pump, and the air exhaufted, the cork will preponderate, and fhew itfelf to be heavier than the lead; but upon letting in the air again, the equilibrium will be reftored. The reason of this is, that fince the air is a fluid, and all bodies lofe as much of their absolute weight in it, as is equal to the weight of their bulk of the fluid, the cork being the larger body, lofes more of its real weight than the lead does; and therefore must in fact be heavier, to balance it under the difadvantage of lofing fome of its weight : which difadvantage being taken off by removing the air, the bodies then gravitate according to their real quantities of matter, and the cork, which balanced the lead in air, shews itself to be heavier when in vacuo.

29. Set a lighted candle upon the pump, and cover it with a tall receiver. If the receiver holds a gallon, the candle will burn a minute; and then, after having gradually decayed from the first instant, it will go out: which shews, that a constant supply of fresh air is necessary to feed flame; and so it also is for animal life. For a bird kept under a close receiver will soon die, although no air be pumped out; and it is O 2 found

found that, in the diving-bell, a gallon of air is sufficient only for one minute for a man to breathe in.

The moment when the candle goes out, the fmoke will be feen to afcend to the top of the receiver, and there it will form a fort of cloud : but upon exhaulting the air, the fmoke will fall down to the bottom of the receiver, and leave it as clear at the top as it was before it was fet upon the pump. This fhews, that fmoke does not afcend on account of its being pofitively light, but becaufe it is lighter than air; and its falling to the bottom when the air is taken away, fhews, that it is not defitute of weight. So moft forts of wood afcend or fwim in water; and yet there are none who doubt of the wood's having gravity or weight.

30. Set a receiver, which is open at top, upon the air-pump, and cover it with a brafs plate, and wet leather; and having exhaufted it of air, let the air in again at top through an iron pipe, making it pafs through a charcoal flame at the end of the pipe; and when the receiver is full of that air, lift up the cover, and let down a moufe or bird into the receiver, and the burnt air will immediately kill it. If a candle be let down into that air, it will go out directly; but, by letting it down gently, it will purify the air fo far as it goes; and fo, by letting it down more and more, the flame will drive out the bad air, and good air will get in.

31. Set a bell upon a cufhion on the pumpplate, and cover it with a receiver; then fhake the pump to make the clapper ftrike againft the bell, and the found will be very well heard : bur, exhauft the receiver of air, and then, if the clapper be made to ftrike ever fo hard againft the the bell, it will make no found at all; which fhews, that air is abfolutely neceffary for the propagation of found.

32. Let a candle be placed on one fide of a receiver, and viewed through the receiver at fome diftance; then, as foon as the air begins to be exhausted, the receiver will be filled with vapours which rife from the wet leather, by the fpring of the air in it; and the light of the candle being refracted through that medium of vapours, will have the appearance of circles of various colours, of a faint refemblance to those in the rain-bow.

The air-pump was invented by Otho Guerick of Magdeburg, but was much improved by Mr. Boyle, to whom we are indebted for our greateft part of the knowledge of the wonderful properties of the air, demonstrated in the above experiments.

The elaftic air which is contained in many bodies, and is kept in them by the weight of the atmosphere, may be got out of them either by boiling, or by the air-pump, as shewn in the 25th experiment: but the fixed air, which is by much the greater quantity, cannot be got out but by distillation, fermentation, or putrefaction.

If fixed air did not come out of bodies with difficulty, and fpend fome time in extricating itfelf from them, it would tear them to pieces. Trees would be rent by the change of air from a fixt, to an elaftic ftate, and animals would be burft in pieces by the explosion of air in their food.

Dr. Hales found by experiment, that the air in apples is fo much condenfed, that if it were let out into the common air, it would fill a fpace

03

48

48 times as great as the bulk of the apples themfelves; fo that its preffure outwards was equal to 11776 lb. and, in a cubic inch of oak, to 19860 lb. againft its fides. So that if the air was let loofe at once in these fubftances, they would tear every thing to pieces about them with a force superior to that of gunpowder. Hence, in eating apples, it is well that they part with the air by degrees, as they are chewed, and ferment in the fromach, otherwise an apple would be immediate death to him who eats it.

The mixing of fome fubftances with others will release the air from them, all of a fudden, which may be attended with very great danger. Of this we have a remarkable inftance in an experiment made by Dr. Slare; who having put half a dram of oil of carraway-feeds into one glafs, and a dram of compound fpirit of nitre in another, covered them both on the air-pump with a receiver fix inches wide, and eight inches deep, and then exhausted the air, and continued pumping until all that could poffibly be got both out of the receiver, and out of the two fluids, was extricated : then, by a particular contrivance from the top of the receiver, he mixed the fluids together; upon which they produced fuch a prodigious quantity of air, as inftantly blew up the receiver, although it was preffed down by the atmosphere with upwards of 400 pound weight.

N. B. In the 28th Experiment, the cork muft be covered all over with a piece of thin wet bladder glued to it, and not used until it be thoroughly dry.

LECT,

Of Optics.

LECT. VIII.

Of Optics.

IGHT confifts of an inconceivably great , number of particles flowing from a luminous body in all manner of directions; and these particles are fo fmall, as to furpafs all human comprehension.

That the number of particles of light is inconceivably great, appears from the light of a candle; which, if there be no obstacle in the way to obstruct the passage of its rays, will fill all the fpace within two miles of the candle every way, with luminous particles, before it has loft the least fentible part of its substance.

A ray of light is a continued ftream of thefe particles, flowing from any vilible body in a ftraight line: and that the particles themfelves are incomprehenfibly fmall, is manifeft from the following experiment. Make a fmall pin-hole in a piece of black paper, and hold the paper upright on a table facing a row of candles ftanding by one another; then place a fheet of pafteboard at a little diffance behind the paper, and fome of the rays which flow from all the candles through the hole in the paper, will form as many fpecks of light on the pasteboard, as there are candles on the table before the plate : each fpeck The amabeing as diffinct and clear, as if there was only zing one speck from one fingle candle : which they imaliness of the that the particles of light are exceedingly fmall, particles otherwife they could not pais through the hole of light. from fo many different candles without confufion .- Dr. Niewentyt has computed, that there flows more than 6,000,000,000 times as 04

many

Of Optics.

many particles of light from a candle in one fecond of time, as there are grains of fand in the whole earth, fuppoling each cubic inch of it to contain 1,000,000.

These particles, by falling directly upon our eyes, excite in our minds the idea of light. And when they fall upon bodies, and are thereby reflected to our eyes, they excite in us the ideas of these bodies. And as every point of a visible body reflects the rays of light in all manner of directions, every point will be visible in every part to which the light is reflected from it. Thus the object A C B is visible to an eye in any part where the rays Aa, Ab, Ac, Ad, Ae, Ba, Bb, Bc, Bd, Be, and Ca, Cb, Cc, Cd, Ce, come. Here we have thewn the rays as if they were only reflected from the ends A and B, and from the middle point C of the object; every other point being fuppofed to reflect rays in the fame manner. So that wherever a spectator is placed with regard to the body, every point of that part of the furface which is towards him will be visible, when no intervening object ftops the paffage of the light.

As no object can be feen through the bore of a bended pipe, it is evident that the rays of light move in ftraight lines, whilft there is nothing to refract or turn them out of their rectilineal courfe.

While the rays of light continue in any * medium of an uniform denfity, they are ftraight; but when they pass obliquely out of one medium into another, which is either more denfe or more

* Any thing through which the rays of light can pais, is called a medium; -as air, water, glafs, diamond, or even a vacuum.

Plate XV. Fig. 1.

Reflected light.

202

rare,

Of Optics.

rare, they are refracted towards the denfer medium : and this refraction is more or lefs, as the rays fall more or lefs obliquely on the refracting furface which divides the mediums.

To prove this by experiment, fet the empty Fig. 2. veffel ABCD into any place where the fun fhines obliquely, and observe the part where the fhadow of the edge BC falls on the bottom of the veffel at E; then fill the veffel with water, and the fhadow will reach no farther than e; which shews, that the ray a B E, which came ftraight in the open air, just over the edge of the veffel at B to its bottom at E, is refracted by falling obliquely on the furface of the water at Refracted B; and inflead of going on in the rectilineal di- light. rection a BE, it is bent downward in the water from B to e; the whole bend being at the furface of the water: and fo of all the other rays abc.

If a flick be laid over the veffel, and the fun's rays be reflected from a glafs perpendicularly into the veffel, the fhadow of the flick will fail upon the fame part of the bottom, whether the veffel be empty or full, which fhews, that the rays of light are not refracted when they fall perpendicularly on the furface of any medium.

The rays of light are as much refracted by paffing out of water into air, as by paffing out of air into water. Thus, if a ray of light flows from the point e, under water, in the direction e B; when it comes to the furface of the water at B, it will not go on thence in the rectilineal courfe B d, but will be refracted into the line B a. Therefore,

To an eye at e looking through a plane glafs in the bottom of the empty veffel, the point a cannot be feen, becaufe the fide B c of the veffel inter-
interpofes; and the point d will just be feen over the edge of the veffel at B. But if the veffel be filled with water, the point a will be feen from e; and will appear as at d, elevated in the direction of the ray $e B^*$.

The days are made longer by the refraction of the -fun's rays.

The time of fun-rifing or fetting, fuppoling its rays fuffered no refraction, is eafily found by But observation proves that the calculation. fun rifes fooner, and fets later every day than the calculated time; the reason of which is plain, from what was faid immediately above. For, though the fun's rays do not come part of the way to us through water, yet they do through the air or atmosphere, which being a groffer medium than the free fpace between the fun and the top of the atmosphere, the rays, by entering obliquely into the atmosphere, are there refracted. and thence bent down to the earth. And although there are many places of the earth to which the fun is vertical at noon, and confequently his rays can fuffer no refraction at that time, becaufe they come perpendicularly through the atmosphere : yet there is no place to which the fun's rays do not fall obliquely on the top of the atmosphere, at his rifing and fetting; and confequently, no clear day in which the fun will not be visible before he rifes in the horizon, and after he fets in it : and the longer or thorter, as the atmosphere is more or lefs replete with vapours. For, let ABC be part of the earth's furface, D E F the atmosphere that covers it,

Fig. 3.

* Hence a piece of money lying at e_i in the bottom of an empty vefiel, cannot be feen by an eye at a_i , because the edge of the vefiel intervenes; but let the vefiel be filled with water, and the ray $e_i a$ being then refracted at B, will firike the eye at a_i and fo render the money visible, which will appear as if it were raifed up to f in the line a B f.

and

and E B G H the fentible horizon of an obferver at B. As every point of the fun's furface fends out rays of light in all manner of directions, fome of his rays will conftantly fall upon, and enlighten, fome half of the atmosphere; and therefore, when the fun is at I, below the horizon H, those rays which go on in the free fpace I k K preferve a rectilineal courfe until they fall upon the top of the atmosphere; and those which fall fo about K, are refracted at their entrance into the atmosphere, and bent down in the line K m B, to the observer's place at B: and therefore, to him, the fun will appear at L, in the direction of the ray B m K, above the horizon B G H, when he is really below it at I.

The angle contained between a ray of light, and a perpendicular to the refracting furface, is called the angle of incidence; and the angle con-Angle of tained between the fame perpendicular, and the incidence. fame ray after refraction, is called the angle of refraction. Thus, let L B M be the refracting Fig. 4. furface of a medium (fuppofe water) and A B C Angle of a perpendicular to that furface; let D B be a refraction. ray of light, going out of air into water at B, and therein refracted in the line B H; the angle A B D, is the angle of incidence, of which D Fis the fine; and the angle K B H is the angle of refraction, whofe fine is K I.

When the refracting medium is water, the fine of the angle of incidence is to the fine of the angle of refraction, as 4 to 3; which is confirmed by the following experiment, taken from Doctor SMITH's Optics.

Defcribe the circle D A E C on a plane fquare board, and crofs it at right angles with the ftraight lines A B C, and L B M; then, from the interfection, A, with any opening of the compaffes

paffes, fet off the equal arcs AD and AE, and draw the right line DFE: then, taking Fa which is three quarters of the length F E, from the point a, draw a I parallel to A B K, and join K I, parallel to B M: fo K I will be equal to three quarters of FE or of DF. This done, fix the board upright upon the leaden pedeftal O, and flick three pins perpendicularly into the board, at the points $D_1: B_2$, and I: then let the board upright into the veffel VUT, and fill up the veffel with water to the line L B M. When the water has fettled, look along the line D B. fo as you may fee the head of the pin B over the head of the pin D; and the pin I will appear in the fame right line produced to G, for its head will be feen just over the head of the pin at B: which fhews that the ray I B, coming from the pin at I, is fo refracted at B, as to proceed from thence in the line $B \cdot D$ to the eye of the observer; the fame as it would do from any point G in the right line DBG, if there were no water in the veffel : and alfo fhews that K I, the fine of refraction in water, is to D F, the fine of incidence in air, as 3 to 4.*

Hence, if D B H were a crooked flick put obliquely into the water, it would appear a flraight one, as D B G. Therefore, as the line B H appears at B G, fo the line B G will appear at B g; and confequently, a flraight flick D B Gput obliquely into water, will feem bent at the furface of the water in B, and crooked, as D B g.

When a ray of light paffes out of air into glais, the fine of incidence is to the fine of re-

* This is flricily true of the red rays only, for the other coloured rays are differently refracted; but the difference is fo fmall, that it need not be confidered in this place.

fraction,

fraction, as 3 to 2; and when out of air into a diamond, as 5 to 2.

Glass may be ground into eight different Fig. 5. shapes at least, for optical purposes, viz.

i. A plane glass, which is flat on both fides, and of equal thickness in all its parts, as A.

2. A plano convex, which is flat on one fide, Lenfes. and convex on the other, as B.

3. A double convex, which is convex on both fides, as C.

4. A plano-concave which is flat on one fide, and concave on the other, as D.

5. A double-concave, which is concave on both fides, as E.

6. A menifcus, which is concave on one fide, and convex on the other, as F.

7. A flat plano-convex, whole convex fide is ground into feveral little flat furfaces, as G.

8. A prifm, which has three flat fides, and when viewed endwife, appears like an equilateral triangle, as H.

Glaffes ground into any of the fhapes B, C, D, E, F, are generally called *lenfes*.

A right line LIK, going perpendicularly through the middle of a lens, is called *the axis* of the lens.

A ray of light G b, falling perpendicularly on a plane glafs E F, will pafs through the glafs Fig. 6. in the fame direction b i, and go out of it into the air in the fame right course i H.

3

A ray of light AB, falling obliquely on a plane glafs, will go out of the glafs in the fame direction, but not in the fame right line; for in touching the glafs, it will be refracted in the line BC, and in leaving the glafs, it will be refracted in the line CD.

A ray

Fig. 6.

A ray of light C D, falling obliquely on the middle of a convex glafs, will go forward in the fame direction D E, as if it had fallen with the fame degree of obliquity on a plane glafs; and will go out of the glass in the fame direction with which it entered : for it will be equally refracted at the points D and E, as if it had paffed through a plane furface. But the rays C G and C I will be fo refracted, as to meet again at the point F. Therefore, all the rays which flow from the point C, fo as to go through the glafs, will meet again at F; and if they go farther onward, as to L, they crofs at F, and go forward on the opposite fides of the middle ray CD E F, to what they were in approaching it in the directions HF and KF.

Fig. 8. The properties of different lenfes.

Fig. 9.

When parallel rays, as A B C, fall directly upon a plano-convex glass D E, and pass through it, they will be fo refracted, as to unite in a point f behind it: and this point is called the *principal focus*: the diffance of which, from the middle of the glass, is called the *focal diffance*; which is equal to twice the radius of the sphere of the glass's convexity. And,

When parallel rays, as A B C, fall directly upon a glafs D E, which is equally convex on both fides, and pafs through it; they will be fo refracted, as to meet in a point or principal focus f, whofe diftance is equal to the radius or femidiameter of the fphere of the glafs's convexity. But if a glafs be more convex on one fide than on the other, the rule for finding the focal diftance is this; as the fum of the femidiameters of both convexities is to the femidiameter of either, fo is double the femidiameter of the other to the diftance of the focus. Or, divide the

the double product of the radii by their fum, and the quotient will be the diftance fought.

Since all those rays of the fun which pais through a convex glass are collected together in its focus, the force of all their heat is collected into that part; and is in proportion to the common heat of the fun, as the area of the glass is to the area of the focus. Hence we fee the reason why a convex glass causes the fun's rays to burn after paffing through it.

All thefe rays crofs the middle ray in the focus f, and then diverge from it, to the contrary fides, in the fame manner FfG, as they converged in the fpace DfE in coming to it.

If another glafs F G, of the fame convexity as D E, be placed in the rays at the fame diftance from the focus, it will refract them fo, as that after going out of it, they will be all parallel, as a b c; and go on in the fame manner as they came to the first glafs D E, through the fpace A B C; but on the contrary fides of the middle ray B f b: for the ray A D f will go on from f in the direction f G a, and the ray C E f in the direction f F c; and fo of the reft.

The rays diverge from any radiant point, as from a principal focus: therefore, if a candle be placed at f, in the focus of the convex glafs F G, the diverging rays in the fpace F f G will be fo refracted by the glafs, as, that after going out of it, they will become parallel, as shewn in the space c b a.

If the candle be placed nearer the glafs than its focal diftance, the rays will diverge after paffing through the glafs, more or lefs, as the candle is more or lefs diftant from the focus.

If the candle be placed farther from the glafs than its focal diffance, the rays will converge after after paffing through the glafs, and meet in a point which will be more or lefs diftant from the glais, as the candle is nearer to, or farther from its focus; and where the rays meet, they will form an inverted image of the flame of the candle; which may be feen on a paper placed in the meeting of the rays.

Fig. I.

PlateXVI. Hence, if any object ABC be placed beyond the focus F of the convex glafs $d \, e \, f$, fome of the rays which flow from every point of the object, on the fide next the glafs, will fall upon it, and after paffing through it, they will be converged into as many points on the oppofite fide of the glafs, where the image of every point will be formed : and confequently, the image of the whole object, which will be inverted. Thus, the rays Ad, Ae, Af, flowing from the point A, will converge in the fpace d a f, and by meeting at a, will there form the image of the point A. The rays Bd, Be, Bf, flowing from the point B, will be united at b by the refraction of the glafs, and will there form the image of the point B. And the rays Cd, Ce, Cf, flowing from the point C, will be united at c, where they will form the image of the point C. And fo of all the other intermediate points between A and C. The rays which flow from every particular point of the object, and are united again by the glafs, are called pencils of rays.

> If the object A B C be brought nearer to the glafs, the picture a b c will be removed to a greater diftance. For then, more rays flowing from every fingle point, will fall more diverging upon the glafs; and therefore cannot be fo foon collected into the corresponding points behind it. Confequently, if the diftance of the object ABC

ABC be equal to the diffance e B of the focus of the glass, the rays of each pencil will be fo refracted by paffing through the glass, that they will go out of it parallel to each other; as d I, eH, f b, from the point C; dG, eK, f D, from the point B; and d K, e E, f L, from the point A: and therefore, there will be no picture formed behind the glass.

If the focal diftance of the glass, and the diftance of the object from the glass, be known, the diftance of the picture from the glass may be found by this rule, viz. multiply the diftance of the focus by the diffance of the object, and divide the product by their difference; the quotient will be the diffance of the picture.

The picture will be as much bigger or lefs Fig. 1. than the object, as its diftance from the glafs is greater or lefs than the diftance of the object. For, as Be is to eb, fo is AC to ca. So that if ABC be the object, c b a will be the picture; or, if c b a be the object, A B C will be the picture.

Having defcribed how the rays of light, The manflowing from objects and paffing through con- ner of vivex glaffes, are collected into points, and form the images of the objects ; it will be eafy to understand how the rays are affected by passing through the humours of the eye, and are thereby collected into innumerable points on the bottom of the eye, and thereon form the images of the objects which they flow from. For, the different humours of the eye, and particularly the chrystalline humour, are to be confidered as a convex glafs; and the rays in paffing through them to be affected in the fame manner as in paffing through a convex glafs.

P

The

PlateXVL. Fig. 2.

212 -

PlateXVI. The eye is nearly globular. It confifts of three coats and three humours. The part Fig. 2. DHHG of the outer coat, is called the felerotica, the reft D E F G the cornea. Next within this coat is that called the choroides, which ferves as it were for a lining to the other, and joins with the iris m n, m n. The iris is compofed of two fets of muscular fibres; the one of a circular form, which contracts the hole in the middle called the pupil, when the light would otherwife be too flrong for the eye; and the The eye described. other of radial fibres, tending every where from the circumference of the iris towards the middle of the pupil; which fibres, by their contraction, dilate and enlarge the pupil when the light is weak, in order to let in the more of its rays. The third coat is only a fine expansion of the optic nerve L, which fpreads like net-work all over the infide of the choroides, and is therefore called the retina; upon which are painted (as it were) the images of all visible objects, by the rays of light which either flow or are reflected

from them.

Under the cornea is a fine transparent fluid like water, which is therefore called the aqueous burnour. It gives a protuberant figure to the cornea, fills the two cavities m m and n n, which communicate by the pupil P, and has the fame limpidity, specific gravity, and refractive power as water. At the back of this lies the chrystalline burnour I I, which is shaped like a double convex glas; and is a little more convex on the back than the fore-part. It converges the rays, which pass through it from every visible object to its focus at the bottom of the eye. This humour is transparent like chrystal, is much of the consistence of hard jelly, and exceeds the specific

ipecific gravity of water in the proportion of it to 10. It is inclosed in a fine transparent membrane, from which proceed radial fibres o, called the *ligamentum ciliare*, all around its edge; and join to the circumference of the iris. These fibres have a power of contracting and dilating occasionally, by which means they alter the shape or convexity of the chrystalline humour, and also shift it a little backward or forward in the eye, so as to adapt its focal distance at the bottom of the eye to the different distances of objects; without which provision, we could only see those objects distinctly, that were all at one distance from the eye.

At the back of the chryftalline, lies the vitreous bumour K K, which is transparent like glass, and is largeft of all in quantity, filling the whole orb of the eye, and giving it a globular shape. It is much of a confistence with the white of an egg, and very little exceeds the specific gravity and refractive power of water.

As every point of an object A B C fends out rays in all directions, fome rays, from every point on the fide next the eye, will fall upon the cornea between E and F; and by passing on through the humours and pupil of the eye, they will be converged to as many points on the retina or bottom of the eye, and will thereon form a diffinct inverted picture c b a of the object. Thus, the pencil of rays q r s that flows from the point A of the object, will be converged to the point a on the retina; those from the point B will be converged to the point b; those from the point C will be converged to the point c; and fo of all the intermediate points : by which means the whole image a b c is formed, and the object made visible; although it must P 2 be be owned, that the method by which this fenfation is carried from the eye by the optic nerve to the common fenfory in the brain, and there differend, is above the reach of our comprehension.

But that vision is effected in this manner, may be demonstrated experimentally. Take a bullock's eye whilst it is fresh, and having cut off the three coats from the back part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will see an inverted picture of the object upon the paper.

Seeing the image is inverted, many have wondered why the object appears upright. But we are to confider, 1. That inverted is only a relative term : and 2. That there is a very great difference between the real object and the means or image by which we perceive it. When all the parts of a diftant profpect are painted upon the retina, they are all right with refpect to one another, as well as the parts of the profpect itfelf; and we can only judge of an object's being inverted, when it is turned reverfe to its natural polition, with refpect to other objects which we fee and compare it with .- If we lay hold of an upright flick in the dark, we can tell which is the upper or lower part of it, by moving our hand upward or downward; and know very well that we cannot feel the upper end by moving our hand downward. Tuft fo we find by experience, that upon directing our eyes towards a tail object, we cannot fee its top by turning our eyes downward, nor its foot by turning our eyes upward; but must trace the object the fame way by the eye to fee it from head to foot, as we do by the hand to feel it; 6 and

and as the judgment is informed by the motion of the hand in one cafe, fo it is also by the motion of the eye in the other.

In Fig. 4. is exhibited the manner of fceing Fig. 4the fame object A B C, by both the eyes D and E at once.

When any part of the image c b a falls upon the optic nerve L, the corresponding part of the object becomes invifible. On which account nature has wifely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the fide next the nofe; fo that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point a of the image c b a falls upon the optic nerve of the eye D, but not of the eye E; and the point efalls upon the optic nerve of the eye E, but not of the eve D: and therefore to both eyes taken together, the whole object A B C is visible.

The nearer that any object is to the eye, the Plate larger is the angle under which it it feen, and XVII. the magnitude under which it appears. Thus Fig. 1. to the eye D, the object A B C is feen under the angle APC; and its image c b a is very large upon the retina : but to the eye E, at a double diftance, the fame object is feen under the angle A p C, which is equal only to half the angle A P C, as is evident by the figure. The image c b a is likewife twice as large in the eye D, as the other image c b a is in the eye E. In both these representations, a part of the image falls on the optic nerve, and the object in the correfponding part is invifible.

As the fenfe of feeing is allowed to be occafioned by the impulse of the rays from the visible object upon the retina of the eye, and forming P 3 the

diffance, because they cannot appear under any fensible angle. The method of viewing such minute objects is by a *microscope*, of which there are three forts, viz. the *fingle*, the *double*, and the *folar*.

Fig. 5. The fingle microfcope.

The fingle microscope, is only a finall convex glass, as c d, having the object a b placed in its focus, and the eye at the fame diffance on the other fide; fo that the rays of each pencil, flowing from every point of the object on the fide next the glass, may go on parallel in the fpace between the eye and the glass; and then, by entering the eye at C, they will be converged to as many different points on the retina, and form a large inverted picture A B upon it, as in the figure.

To find how much this glafs magnifies, divide the leaft diftance (which is about fix inches) at which an object can be feen diftinctly with the bare eye, by the focal diftance of the glafs; and the quotient will flow how much the glafs magnifies the diameter of the object.

The double or compound microscope, confifts of an object-glass c d, and an eye glass e f. The fmall object a b is placed at a little greater diftance from the glafs c d than its principal focus, fo that the pencils of rays flowing from the dif. ferent points of the object, and paffing through the glass, may be made to converge and unite in as many points between g and b, where the image of the object will be formed : which image is viewed by the eye through the eye-For the eye-glass being fo placed, glais e f. that the image g b may be in its focus, and the eye much about the fame diftance on the other fide, the rays of each pencil will be parallel, after going out of the eye-glafs, as at e and f_{2} till

Fig. 6. The double miarofcope. till they come to the eye at k, where they will begin to converge by the refractive power of the humours; and after having croffed each other in the pupil, and paffed through the chryftalline and vitreous humours they will be collected into points on the retina, and form the large inverted image A B thereon.

The magnifying power of this microfcope is Suppose the image g b to be fix as follows. times the diftance of the object a b from the object glafs c d; then will the image be fix times the length of the object : but fince the image could not be feen diffinctly by the bare eye at a lefs diftance than fix inches, if it be viewed by an eye-glass ef, of one inch focus, it will thereby be brought fix times nearer the eye; and confequently viewed under an angle fix times as large as before; fo that it will be again magnified fix times ; that is, fix times by the objectglafs, and fix times by the eye-glafs, which multiplied into one another, makes 36 times; and fo much is the object magnified in diameter more than what it appears to the bare eye; and confequently 36 times 36, or 1296 times in furface.

But becaufe the extent or field of view is very fmall in this microfcope, there are generally two eye-glaffes placed fometimes clofe together, and fometimes an inch afunder; by which means, although the object appears lefs magnified, yet the vifible area is much enlarged by the interpofition of a fecond eye-glafs; and confequently a much pleafanter view is obtained.

The folar microfcope, invented by Dr. Lie-Fig. 7. berkhun, is conftructed in the following manner. The folar Having procured a very dark room, let a round microfcope. hole be made in the window-fhutter, about three inches inches diameter, through which the fun may caft a cylinder of rays A A into the room. In this hole, place the end of a tube, containing two convex glaffes and an object, viz. I. A convex glafs a a, of about two inches diameter, and three inches focal diftance, is to be placed in that end of the tube which is put into the hole. 2. The object b b, being put between two glaffes (which muft be concave to hold it at liberty) is placed about two inches and a half from the glafs a a. 3. A little more than a quarter of an inch from the object is placed the fmall convex glafs c c, whofe focal diftance is a quarter of an inch.

The tube may be fo placed, when the fun is low, that his rays A A may enter directly into it: but when he is high, his rays B B muft be reflected into the tube by the plane mirrour or looking-glafs C C.

Things being thus prepared, the rays that enter the tube will be conveyed by the glafs a a towards the object b b, by which means it will be ftrongly illuminated; and the rays d which flow from it, through the magnifying glafs c c, will make a large inverted picture of the object at D D, which, being received on a white paper, will represent the object magnified in length, in proportion of the diffance of the picture from the glafs c c, to the diffance of the object from the fame glafs. Thus, fuppole the diftance of the object from the glass to be $\frac{3}{10}$ parts of an inch, and the diftance of the diftinct picture to be 12 feet or 144 inches, in which there are 1440 tenths of an inch; and this number divided by 3 tenths, gives 480; which is the number of times the picture is longer or broader than the object; and the length multiplied by the breadth, fhews how much the whole furface is magnified.

Before

Before we enter upon the defcription of tele-Telefcopes. fcopes, it will be proper to fhew how the rays of light are affected by paffing through concave glaffes, and alfo by falling upon concave mirrours.

When parallel rays, as a b c d e f g b, pafs Plate. directly through a glafs A B, which is equally XVIII. concave on both fides, they will diverge after Fig. 1, paffing through the glafs, as if they had come from a radiant point C, in the center of the glafs's concavity; which point is called the negative or virtual focus of the glafs. Thus the ray a, after paffing through the glafs A B, will go on in the direction k l, as if it had proceeded from the point C, and no glafs been in the way, The ray b will go on in the direction m n; the ray c in the direction o p, &c.—The ray C, that falls directly upon the middle of the glafs, fuffers no refraction in paffing through it; but goes on in the fame rectilineal direction, as if no glafs had been in its way.

If the glafs had been concave only on one fide, and the other fide quite plane, the rays would have diverged, after paffing through it, as if they had come from a radiant point at double the diffance of C from the glafs; that is, as if the radiant had been at the diffance of a whole diameter of the glafs's concavity.

If rays come more converging to fuch a glafs, than parallel rays diverge after paffing through it, they will continue to converge after paffing through it; but will not meet fo foon as if no glafs had been in the way; and will incline towards the fame fide to which they would have diverged, if they had come parallel to the glafs. Thus the rays f and b, going in a converging flate towards the edge of the glafs at B, and conconverging more in their way to it that the parallel rays diverge after paffing through it, they will go on converging after they pafs through it, though in a lefs degree than they did before, and will meet at I: but if no glafs had been in their way, they would have met at i.

When the parallel rays, as d f a, C m b, e l c, fall upon a concave mirror AB (which is not transparent, but has only the furface A b B of a clear polifh) they will be reflected back from that mirror, and meet in a point m, at half the diftance of the furface of the mirror from C, the center of its concavity: for they will be reflected at as great an angle from the perpendicular to the furface of the mirror, as they fell upon it, with regard to that perpendicular; but on the other fide thereof. Thus, let C be the center of concavity of the mirror A b B, and let the parallel rays df a, C m b, and e l c, fall upon it at the points a b, and c. Draw the lines C i a, C m b, and C b c, from the center C to these points; and all these lines will be perpendicular to the furface of the mirror, becaufe they proceed thereto like fo many radii or fpokes from its center. Make the angle C a b equal to the angle d a C, and draw the line a m b, which will be the direction of the ray $d f a_{1}$ after it is reflected from the point a of the mirror : fo that the angle of incidence $d \in C$, is equal to the angle of reflection C a b; the rays making equal angles with the perpendicular Ci a on its oppolite fides.

Draw alfo the perpendicular $C \ b \ c$ to the point c, where the ray $e \ l \ c$ touches the mirror; and, having made the angle $C \ c \ i$, equal to the angle $C \ c \ c$, draw the line $c \ m \ i$, which will be the courfe

Fig. 2.

course of the ray e l c, after it is reflected from the mirror.

The ray C m b paffes through the center of concavity of the mirror, and falls upon it at b, the perpendicular to it; and is therefore reflected back from it in the fame line b m C.

All these reflected rays meet in the point m; and in that point the image of the body which emits the parallel rays da, Cb, and ec, will be formed: which point is diftant from the mirror equal to half the radius bm C of its concavity.

The rays which proceed from any celeftial object may be effected parallel at the earth, and therefore, the images of that object will be formed at *m*, when the reflecting furface of the concave mirror is turned directly towards the object. Hence, the focus *m* of parallel rays is not in the center of the mirror's concavity, but half way between the mirror and that center.

The rays which proceed from any remote terrestrial object, are nearly parallel at the mirror; not strictly fo, but come diverging to it, in feparate pencils, or, as it were, bundles of rays, from each point of the fide of the object next the mirror : and therefore they will not be converged to a point, at the diftance of half the radius of the mirror's concavity from its reflecting furface; but into separate points at a little greater diftance from the mirror. And the nearer the object is to the mirror, the farther these points will be from it; and an inverted image of the object will be formed in them, which will feem to hang pendent in the air; and will be feen by an eye placed beyond * (with regard to the mirror) in all respects like

like the object, and as diffinct as the object itfelf.

Fig. 3.

Let A c B be the reflecting furface of a mirror, whole center of concavity is at C; and let the upright object D E be placed beyond the center C, and fend out a conical pencil of diverging rays from its upper extremity D, to every point of the concave furface of the mirror A c B. But to avoid confusion, we only draw three rays of that pencil, as D A, D c, D B.

From the center of concavity C, draw the three right-lines CA, Cc, CB, touching the mirror in the fame points where the forefaid rays touch it; and all thefe lines will be perpendicular to the furface of the mirror. Make the angle C A d equal to the angle D A C, and draw the right line A d for the course of the reflected ray DA: make the angle C c d equal to the angle D c C, and draw the right line c d for the courfe of the reflected ray D d: make alfo the angle C B d equal to the angle D B C, and draw the right line B d for the course of the reflected ray D B. All these reflected rays will meet in the point d, where they will form the extremity d of the inverted image e d, fimilar to the extremity D of the upright object D E.

If the pencils of rays E f, E g, E b be alfo continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from D, they will all meet at the point e by reflection, and form the extremity e of the image e d, fimilar to the extremity E of the object D E.

And as each intermediate point af the object, between D and E, fends out a pencil of rays in like manner to every part of the mirror, the rays

rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities e and d of the image; and fo the whole image will be formed, not at i, half the diffance of the mirror from its center of concavity C; but at a greater diffance, between i and the object D E; and the image will be inverted with refpect to the object.

This being well underftood, the reader will eafily fee how the image is formed by the large concave mirror of the reflecting telefcope, when he comes to the defcription of that inftrument.

When the object is more remote from the mirror than its center of concavity C, the image will be lefs than the object, and between the object and mirror : when the object is nearer than the center of concavity, the image will be more remote and bigger than the object : thus, if D E be the object, e d will be its image; for, as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it; on account of the leffer or greater divergency of the pencils of rays which proceed from the object; for, the lefs they diverge, the fooner they are converged to points by reflection; and the more they diverge, the farther they must be reflected before they meet.

If the radius of the mirror's concavity and the diftance of the object from it be known, the diftance of the image from the mirror is found by this rule: divide the product of the diftance and radius by double the diftance made lefs by the radius, and the quotient is the diftance required.

If

If the object be in the center of the mirror's concavity, the image and object will be coincident, and equal in bulk.

If a man places himfelf directly before a large concave mirror, but farther from it than its center of concavity, he will fee an inverted image of himfelf in the air, between him and the mirror, of a lefs fize than himfelf. And if he holds out his hand towards the mirror. the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the center of concavity; and he will imagine he may shake hands with his image. If he reaches his hand farther, the hand of the image will pass by his hand, and come between his hand and his body : and if he moves his hand towards either fide, the hand of the image will move towards the other; fo that whatever way the object moves, the image will move the contrary way.

All the while a by-ftander will fee nothing of the image, because none of the reflected rays that form it enter his eyes.

If a fire be made in a large room, and a fmooth mahogany table be placed at a good diftance near the wall, before a large concave mirror, fo placed, that the light of the fire may be reflected from the mirror to its focus upon the table; if a perfon ftands by the table, he will fee nothing upon it but a longifh beam of light: but if he ftands at a diftance towards the fire, not directly between the fire and mirror, he will fee an image of the fire upon the table, large and erect. And if another perfon, who knows nothing of this matter beforehand, fhould chance to come into the room, and fhould look from the fire towards the table, he

he would be frartled at the appearance; for the Plate table would feem to be on fire, and by being XVIII. near the wainfcot, to endanger the whole houfe. In this experiment, there fhould be no light in the room but what proceeds from the fire; and the mirror ought to be at leaft fifteen inches in diameter.

If the fire be darkened by a fcreen, and a large candle be placed at the back of the fcreen; a perfon ftanding by the candle will fee the appearance of a fine large ftar, or rather planet, upon the table, as bright as Venus or Jupiter. And if a fmall wax taper (whole flame is much lefs than the flame of the candle) be placed near the candle, a fatellite to the planet will appear on the table: and if the taper be moved round the candle, the fatellite will go round the planet.

For thefe two pleafing experiments, I am indebted to the late reverend Dr. Long, *Lowndes*'s profeffor of aftronomy at Cambridge, who favoured me with the fight of them, and many more of his curious inventions.

In a refraining telescope, the glafs which is The reneareft the object in viewing it, is called the fracting object-glass; and that which is neareft the eye, telescope, is called the eye-glass. The object-glafs must be convex, but the eye-glafs may be either convex or concave: and generally, in looking through a telescope, the eye is in the focus of the eye-glafs; though that is not very material: for the diffance of the eye, as to diffinct vision, is indifferent, provided the rays of the pencils fall upon it parallel: only, the nearer the eye is to the end of the telescope, the larger is the fcope or area of the field of view.

Let c d be a convex-glass fixed in a long tube, and have its focus at E. Then, a pencil of rays

ghi,

g b i, flowing from the upper extremity A of the remote object A B, will be fo refracted by paffing through the glass, as to converge and meet in the point f; whilft the pencil of rays k lm flowing from the lower extremity B, of the fame object A B, and paffing through the glafs, will converge and meet in the point e: and the images of the points A and B, will be formed in the points f and e. And as all the intermediate points of the object, between A and B, fend out pencils of rays in the fame manner, a fufficient number of these pencils will pass through the object glass c d, and converge to as many intermediate points between e and f; and fo will form the whole inverted image e E f, of the diffinct object. But becaufe this image is fmall, a concave glafs n o is fo placed in the end of the tube next the eye, that its virtual focus may be at F. And as the rays of the pencils pais converging through the concave glafs, but converge lefs after paffing through it than before, they go on further, as to b and a, before they meet; and the pencils themfelves being made to diverge by paffing through the concave glafs, they enter the eve, and form the large picture a b upon the retina, whereon it is magnified under the angle bFa.

But this telescope has one inconveniency which renders it unfit for most purposes, which is, that the pencils of rays being made to diverge by paffing through the concave glass z o, very few of them can enter the pupil of the eye; and therefore the field of view is but very small, as is evident by the figure. For none of the pencils which flow either from the top or bottom of the object A B can enter the pupil of the eye at C, but are all ftopt by falling upon the iris above

above and below the pupil : and therefore, only the middle part of the object can be feen when the telefcope lies directly towards it, by means of those rays which proceed from the middle of the object. So that to fee the whole of it, the telescope must be moved upwards and downwards, unlefs the object be very remote; and then it is never feen diffinctly.

This inconvenience is remedied by fubftitut- Fig. 5. ing a convex eye-glass, as g b, in place of the concave one; and fixing it fo in the tube, that its focus may be coincident with the focus of the object-glafs c d, as at E. For then, the rays of the pencils flowing from the object A B, and paffing through the object glass c d, will meet in its focus, and form the inverted image m E p: and as the image is formed in the focus of the eye-glass g b, the rays of each pencil will be parallel, after paffing through that glass; but the pencils themfelves will crofs in its focus, on the other fide, as at e: and the pupil of the eye being in this focus, the image will be viewed through the glafs, under the angle $g \in b$; and being at E, it will appear magnified, fo as to fill the whole fpace C m e p D.

But, as this telescope inverts the image with respect to the object, it gives an unpleafant view of terreftrial objects; and is only fit for viewing the heavenly bodies, in which we regard not their polition, because their being inverted does not appear, on account of their being round. But whatever way the object feems to move, this telefcope must be moved the contrary way, in order to keep fight of it; for, fince the object is inverted, its motion will be fo too.

The magnifying power of this telefcope is, as the focal diltance of the object-glais to the focal Q 2

focal diftance of the eye-glass. Therefore, if the former be divided by the latter, the quotient will express the magnifying power.

When we speak of magnifying by a telefcope or microfcope, it is only meant with regard to the diameter, not to the area or folidity of the object. But as the inftrument magnifies the vertical diameter, as much as it does the horizontal, it is eafy to find how much the whole vilible area or furface is magnified : for, if the diameters be multiplied into one another, the product will express the magnification of the whole visible Thus, suppose the focal distance of the area, object-glass be ten times as great as the focal diftance of the eve-glafs; then, the object wilk be magnified ten times, both in length and breadth: and 10 multiplied by 10, produces 100; which flews, that the area of the object will appear 100 times as big when feen through fuch a telescope, as it does to the bare eye.

Hence it appears, that if the focal diftance of the eye-glafs, were equal to the focal diftance of the object-glafs, the magnifying power of the telefcope would be nothing.

This telefcope may be made to magnify in any given degree, provided it be of a fufficient length. For, the greater the focal diffance of the object-glafs, the lefs may be the focal diftance of the eye-glafs; though not directly in proportion. Thus, an object-glafs, of 10 feet focal diffance, will admit of an eye glafs whole focal diffance is little more than 2[±] inches; which will magnify near 48 times : but an object-glafs, of 100 feet focus, will require an eyeglafs fomewhat more than 6 inches; and will therefore magnify almost 200 times.

A telefcope for viewing terreftrial objects, fhould be fo conftructed, as to fhew them in their natural pofture.

posture. And this is done by one object-glass Fig. 6. c d, and three eye-glaffes e f, g b, i k, fo placed, that the diftance between any two, which are nearest to each other, may be equal to the fum of their focal diftances; as in the figure, where the focus of the glaffes c d and e f meet at F, those of the glasses e f and g b, meet at l, and of g b and i k, at m; the eye being at n, in or near the focus of the eye-glass i k, on the other fide. Then, it is plain, that these pencils of rays, which flow from the object AB, and pais through the object-glafs c d, will meet and form an inverted image CFD in the focus of that glafs; and the image being also in the focus of the glass ef, the rays of the pencils will become parallel, after paffing through that glafs, and crofs at l, in the focus of the glafs ef; from whence they pass on to the next glass g b, and by going through it they are converged to points in its other focus, where they form an erect image E m F, of the object A B: and as this image is alfo in the focus of the eye-glafs i k, and the eye on the opposite fide of the fame glass; the image is viewed through the eye-glats in this telefcope, in the fame manner as through the eye-glafs in the former one; only in a contrary polition, that is, in the fame polition with the object.

The three glaffes next the eye, have all their focal diftances equal: and the magnifying power of this telescope is found the fame way as that of the last above; viz. by dividing the focal diftance of the object-glass c d, by the focal distance of the eye-glass i k, or g b, or ef, fince all these three are equal.

When the rays of light are feparated by refraction, they become coloured, and if they be united again, they will be a perfect white. But thofe

3

pears coloured

232

Why the those rays which pass through a convex glass, object ap- near its edges are more unequally refracted than those which are nearer the middle of the glass. when feen And when the rays of any pencil are unequally through a refracted by the glafs, they do not all meet telescope. again in one and the same point, but in separate

points; which makes the image indiffinct, and coloured, about its edges. The remedy is, to have a plate with a fmall round hole in its middle, fixed in the tube at m, parallel to the glaffes. For, the wandering rays about the edges of the glaffes will be ftopt, by the plate, from coming to the eye : and none admitted but those which come through the middle of the glass, or at least at a good diftance from its edges, and pafs through the hole in the middle of the plate. But this circumferibes the image, and leffens the field of view, which would be much larger if the place could be difpenfed with.

The refletting telescope.

The great inconvenience attending the management of long telefcopes of this kind, has brought them much into difuse ever fince the reflecting telescope was invented. For one of this fort, fix feet in length, magnifies as much as one of the other an hundred. It was invented by Sir Ifaac Newton, but has received confiderable improvements fince his time; and is now generally constructed in the following manner, which was first proposed by Dr. Gregory.

Fig. 7.

At the bottom of the great tube TTT is placed the large concave mirror DUVF, whofe principal focus is at m; and in its middle is a round hole P, opposite to which is placed the fmall mirror L, concave toward the great one; and fo fixed to a ftrong wire M, that it may be moved farther from the great mirror, or nearer to it, by means of a long fcrew on the out-

outfide of the tube, keeping its axis ftill in the fame line P m n with that of the great one .--Now, fince in viewing a very remote object, we can fcarce fee a point of it but what is at leaft as broad as the great mirror, we may confider the rays of each pencil, which flow from every point of the object, to be parallel to each other, and to cover the whole reflecting furface D U V F. But to avoid confusion in the figure, we shall only draw two rays of a pencil flowing from each extremity of the object into the great tube, and trace their progrefs, through all their reflections and refractions, to the eye f, at the end of the fmall tube t t, which is joined to the great one.

Let us then suppose the object A B to be at fuch a diftance, that the rays C may flow from its lower extremity B, and the rays E from its upper extremity A. Then the rays C falling parallel upon the great mirror at D, will be thence reflected, converging in the direction DG; and by croffing at I in the principal focus of the mirror, they will form the upper extremity I of the inverted image I K, fimilar to the lower extremity B of the object A B: and paffing on to the concave mirror L (whole focus is at n) they will fall upon it at g, and be thence reflected converging, in the direction g N, becaufe g m is longer than g n; and paffing through the hole P in the large mirror, they would meet fomewhere about r, and form the lower extremity d of the erect image a d, fimilar to the lower extremity B of the object A B. But by paffing through the plano-convex-glafs R in their way, they form that extremity of the image at b. In like manner, the rays E, which come from the top of the object A B, and fall parallel upon the great mirror at F, are thence reflected converg-Q4 ing

ing to its focus, where they form the lower extremity K of the inverted image IK, fimilar to the upper extremity A of the object AB; and thence paffing on to the fmall mirror L, and falling upon it at b, they are thence reflected in the converging flate bO; and going on through the hole P of the great mirror, they will meet fomewhere about q, and form there the upper extremity a of the erect image a d, fimilar to the upper extremity A of the object AB: but by paffing through the convex glafs R in their way, they meet and crofs fooner, as at a, where that point of the crect image is formed .- The like being underftood of all those rays which flow from the intermediate points of the object, between A and B, and enter the tube TT; all the intermediate points of the image between a and b will be formed : and the rays paffing on from the image through the eye-glass S, and through a fmall hole e in the end of the leffer tube t t, they enter the eye f_{1} which fees the image a d(by means of the eye-glafs) under the large angle c e d, and magnified in length, under that -angle from c to d.

In the beft reflecting telefcopes, the focus of the finall mirror is never coincident with the focus m of the great one, where the first image IK is formed, but a little beyond it (with refpect to the eye) as at n: the confequence of which is, that the rays of the pencils will not be parallel after reflection from the fmall mirror, but converge fo as to meet in points about q, e, r; where they will form a larger upright image than e d, if the glafs R was not in their way: and this image might be viewed by means of a fingle eye-glafs properly placed between the image and the eye: but then the field of view would be lefs,

lefs, and confequently not fo pleafant; for which reafon, the glafs R is ftill retained, to enlarge the fcope or area of the field.

To find the magnifying power of this telefcope, multiply the focal diffance of the great mirror by the diffance of the fmall mirror from the image next the eye, and multiply the focal diffance of the fmall mirror by the focal diftance of the eye-glafs: then, divide the product of the former multiplication by the product of the latter, and the quotient will express the magnifying power.

I fhall here fet down the dimensions of one of Mr. Sbort's reflecting telescopes, as described in Dr. Smith's Optics.

The focal diftance of the great mirror 9.6 inches, its breadth 2.3; the focal diftance of the fmall mirror 1.5, its breadth 0.6: the breadth of the hole in the great mirror 0.5; the diftance between the fmall mirror and the next eye-glafs 14.2; the diftance between the two eye-glaffes 2.4; the focal diftance of the eye-glafs next the metals 3.8; and the focal diftance of the eyeglafs next the eye 1.1.

One great advantage of the reflecting telefcope is, that it will admit of an eye-glafs of a much fhorter focal diffance than a refracting telefcope will; and, confequently, it will magnify fo much the more: for the rays are not coloured by reflection from a concave mirror, if it be ground to a true figure, as they are by paffing through a convex-glafs, let it be ground ever fo true.

The adjusting forew on the outfide of the great tube fits this telescope to all forts of eyes, by bringing the small mirror either nearer to the eye, or removing it farther: by which means,
means, the rays are made to diverge a little for fhort-fighted eyes, or to converge for those of a long fight.

The nearer an object is to the telescope, the more its pencils of rays will diverge before they fall upon the great mirror, and therefore they will be the longer of meeting in points after reflection; fo that the first image I K will be formed at a greater diftance from the large mirror, when the object is near the telescope, than when it is very remote. But as this image muft be formed farther from the small mirror than its principal focus n, this mirror must be always fet at a greater diftance from the large one, in viewing near objects, than in viewing remote ones. And this is done by turning the forew on the outfide of the tube, until the fmall mirror be fo adjusted, that the object (or rather its image) appears perfect.

In looking through any telescope towards an object, we never fee the object itfelf, but only that image of it which is formed next the eye in the telescope. For, if a man holds his finger or a flick between his bare eye and an object, it will hide part (if not the whole) of the object from his view. But if he ties a flick across the mouth of a telescope, before the object-glass, it will hide no part of the imaginary object he faw through the telescope before, unless it covers the whole mouth of the tube : for, all the effect will be, to make the object appear dimmer, because it intercepts part of the rays. Whereas, if he puts only a piece of wire across the infide of the tube, between the eye-glafs and his eye, it will hide part of the object which he thinks he fees : which proves that he fees not the real object, but its image. This is also confirmed by means of the fmall

Of Optics.

fmall mirror L, in the reflecting telescope, which is made of opake metal, and ftands directly between the eye and the object towards which the telescope is turned; and will hide the whole object from the eye at e, if the two glaffes R and S are taken out of the tube.

The multiplying glafs is made by grinding PlateXIX. down the round fide b i k of a convex glafs A B Fig. 1. into feveral flat furfaces, as b b, bld, dk. An ob- The mulject C will not appear magnified, when teen tiplyingthrough this glafs, by the eye at H; but it will glafs. appear multiplied into as many different objects as the glais contains plane furfaces. For, fince rays will flow from the object C to all parts of the glafs, and each plane furface will refract thefe rays to the eye, the fame object will appear to the eye, in the direction of the rays which enter it through each furface. Thus, a ray g i H, falling perpendicularly on the middle furface will go through the glafs to the eye without fuffering any refraction; and will therefore thew the object in its true place at C: whilft a ray a b flowing from the fame object, and falling obliquely on the plane furface b b, will be refracted in the direction be, by paffing through the glafs; and upon leaving it, will go on to the eye in the direction e H; which will caufe the fame object C to appear alfo at E, in the direction of the ray He, produced in the right line Hen. And the ray c d, flowing from the object C, and falling obliquely on the plane furface d k, will be refracted (by palling through the glafs and leaving it at f) to the eye at H; which will cause the fame object to appear at D, in the direction H f m .--If the glafs be turned round the line g l H, as an axis, the object C will keep its place, becaufe the furface bld is not removed; but all the other

238

Fig. 2. The camera ob= foura.

other objects will feem to go round C, becaufe the oblique planes, on which the rays a b, c d fall, will go round by the turning of the glafs.

The camera obfcura is made by a convex glafs CD, placed in a hole of a window-fhutter. Then, if the room be darkened to as no light can enter but what comes through the glafs, the pictures of all the objects (as fields, trees, buildings, men, cattle, &cc.) on the outfide, will be fhewn in an inverted order, on a white paper placed at GH in the focus of the glafs; and will afford a most beautiful and perfect piece of perspective or landscape of whatever is before the glafs; efpecially if the fun fhines upon the objects.

If the convex glafs C D be placed in a tube in the fide of a fquare box, within which is the plane mirror E F, reclining backwards in an angle of 45 degrees from the perpendicular k q, the pencils of rays flowing from the outward objects, and paffing through the convex glafs to the plane mirror, will be reflected upwards from it, and meet in points, as I and K (at the fame diffance that they would have meet at H and G, if the mirror had not been in the way) and will form the aforefaid images on an oiled paper ftretched horizontally in the direction IK; on which paper, the out-lines of the images may be eafily drawn with a black lead pencil; and then copied on a clean fheet, and coloured by art, as the objects themfelves are by nature .---In this machine, it is ufual to place a plane glafs, unpolifhed, in the horizontal fituation IK, which glass receives the images of the outward objects; and their outlines may be traced upon it by a black-lead pencil.

3 100 a 1 100 N. B.

Of Optics.

N. B. The tube in which the convex glafs C D is fixed, must be made to draw out, or push in, fo as to adjust the distance of that glafs from the plane mirror, in proportion to the distance of the outward objects; which the operator does, until he fees their images distinctly painted on the horizontal glafs at I K.

The forming a horizontal image, as IK, of an upright object AB, depends upon the angles of incidence of the rays upon the plane mirror E F. being equal to their angles of reflection from it. For, if a perpendicular be supposed to be drawn to the furface of the plane mirror at e, where the ray A a C e falls upon it, that ray will be reflected upwards in an equal angle with the other fide of the perpendicular, in the line ed I. Again, if a perpendicular be drawn to the mirror from the point f, where the ray Abf falls upon it, that ray will be reflected in an equal angle from the other fide of the perpendicular, in the line f b I. And if a perpendicular be drawn from the point g, where the ray Acg falls upon the mirror, that ray will be reflected in an equal angle from the other fide of the perpendicular, in the line gil. So that all the rays of the pencil a b c, flowing from the upper extremity of the object AB, and paffing through the convex glafs C D, to the plane mirror E F, will be reflected from the mirror and meet at I, where they will form the extremity I of the image IK, fimilar to the extremity A of the object AB. The like is to be understood of the pencil qrs, flowing from the lower extremity of the object A B, and meeting at K (after reflection from the plane mirror) the rays form the extremity K of the image, fimilar to the extremity B of the object : and fo of all the pencils that flow from the intermediate

Of Optics.

termediate points of the object to the mirror. through the convex glafs.

If a convex glafs, of a fhort focal diftance, be placed near the plane mirror, in the end of a fhort tube, and a convex glafs be placed in a hole in the fide of the tube, fo as the image may be formed between the laft-mentioned convex glafs, and the plane mirror, the image being viewed through this glafs will appear magnified. -In this manner the opera-glasses are constructed; with which a gentleman may look at any lady at a diftance in the company, and the lady know nothing of it.

mon looking glass.

Fig. 3.

The image of any object that is placed before The corr a plane mirror, appears as big to the eye as the object itfelf; and is crect, diftinct, and feemingly as far behind the mirror, as the object is before it : and that part of the mirror, which reflects the image of the object to the eye (the eye being fuppofed equally diffant from the glafs with the object) is just half as long and half as broad as the object itfelf. Let A B be an object placed before the reflecting furface g b i of the plane mirror CD; and let the eye be at o. Let A b be a ray of light flowing from the top A of the object, and falling upon the mirror at b: and b m be a perpendicular to the furface of the mirror at b, the ray A b will be reflected from the mirror to the eye at o, making an angle $m \ b \ o$ equal to the angle $A \ b \ m$: then will the top of the image E appear to the eye in the direction of the reflected ray o b produced to E, where the right line A p E, from the top of the object, cuts the right line o b E, at E. Let B i be a ray of light proceeding from the foot of the object at B to the mirror at i, and n i a perpendicular to the mirror from the point i, where

The operaglass.

where the ray B i falls upon it : this ray will be reflected in the line i o, making an angle n i o, equal to the angle Bin, with that perpendicular, and entering the eye at o: then will the foot F of the image appear in the direction of the reflected ray o i, produced to F, where the right line BF cuts the reflected ray produced to F. All the other rays that flow from the intermediate points of the object AB, and fall upon the mirror between b and i, will be reflected to the eve at o; and all the intermediate points of the image E F will appear to the eye in the direction-line of these reflected rays produced. But all the rays that flow from the object, and fall upon the mirror above b, will be reflected back above the eye at o; and all the rays that flow from the object, and fall upon the mirror below i, will be reflected back below the eye at o: fo that none of the rays that fall above b, or below i, can be reflected to the eye at o; and the diftance between b and i is equal to half the length of the object A B.

Hence it appears, that if a man fee his whole A man image in a plane looking-glafs, the part of the will fee glafs that reflects his image muft be juft half as his image long and half as broad as himielf, let him ftand lookingat any diftance from it whatever; and that his glass, that image must appear just as far behind the glafs as is but image mult appear juit as far betning the Briewing half his he is before it. Thus, the man A B viewing height. himfelf in the plane mirror C D, which is just Fig. 4. half as long as himfelf, fees his whole image as at E F, behind the glafs, exactly equal to his own fize. For, a ray AC proceeding from his eye at A, and falling perpendicularly upon the furface of the glafs at C, is reflected back to his eye in the fame line CA; and the eye of his image will appear at E_1 in the fame line produced

duced to E, beyond the glafs. And a ray BD, flowing from his foot, and falling obliquely on the glafs at D, will be reflected as obliquely on the other fide of the perpendicular $a \ b \ D$, in the direction $D \ A$; and the foot of his image will appear at F, in the direction of the reflected ray AD, produced to F, where it is cut by the right line BGF, drawn parallel to the right line ACE. Juft the fame as if the glafs were taken away, and a real man flood at F, equal in fize to the man flanding at B: for to his eye at A, the eye of the other man at E would be feen in the direction of the line ACE; and the foot of the man at F would be feen by the eye A, in the direction of the line ADF.

If the glafs be brought nearer the man AB_2 as fuppole to cb, he will fee his image as at CDG: for the reflected ray CA (being perpendicular to the glafs) will fhew the eye of the image as at C; and the incident ray Bb, being reflected in the line bA, will fhew the foot of his image as at G; the angle of reflection abA being always equal to the angle of incidence Bba: and fo of all the intermediate rays from A to B. Hence, if the man AB advances towards the glafs CD, his image will approach towards it; and if he recedes from the glafs, his image will alfo recede from it.

Having already fhewn, that the rays of light are refracted when they pass obliquely through different mediums, we come now to prove that fome rays are more refrangible than others; and that, as they are differently refracted, they excite in our minds the ideas of different colours. This will account for the colours feen about the edges of the images of those objects which are viewed through fome telescopes.

Let

Of Optics.

Let the fun fhine into a dark room through a Fig. 5. fmall hole, as at ee, in a window-fhutter; and place a triangular prifm BC in the beam of rays A, in fuch a manner, that the beam may fall obliquely on one of the fides a b C of the prifm. The rays will fuffer different refractions by paf- The fing through the prifm, fo that inftead of going prifm. all out of it on the fide d c C, in one direction, they will go on from it in the different directions reprefented by the lines f, g, b, i, k, l, m, n; and falling upon the oppofite fide of the room, or on white paper placed as at p q to receive them, they will paint upon it a feries of most beautiful lively colours (not to be equalled by art) in this The coorder, viz. those rays which are least refracted by lours of the prifm, and will therefore go on between the the light, lines n and m, will be of a very bright intenfe red at n, degenerating from thence gradually into an orange colour, as they are nearer the line m: the next will be of a fine orange colour at m, and from thence degenerate into a yellow colour towards l: at l they will be of a fine yellow, which will incline towards a green, more and more, as they are nearer and nearer k: at k they will be a pure green, but from thence towards i they will incline gradually to a blue : at i they will be a perfect blue, inclining to an indigo colour from thence towards b; at b they will be quite the colour of indigo, which will gradually change towards a violet, the nearer they are to g: and at g they will be of a fine violet colour, which will incline gradually to a red as they come nearer to f, where the coloured image ends.

There is not an equal quantity of rays in each of these colours; for, if the oblong image pqbe divided into 360 equal parts, the red space R R will

R will take up 45 of thefe parts: the orange O, 27; the yellow \mathcal{X} , 48; the green G, 60; the blue B, 60; the indigo I, 40; and the violet V, 80; all which fpaces are as nearly proportioned in the figure as the finall fpace q p would admit of.

If all these colours be blended together again, they will make a pure white; as is proved thus. Take away the paper on which the colours p qfell, and place a large convex glass D in the rays f, g, b, &c. which will refract them fo, as to make them unite and cross each other at W: where, if **a** white paper be placed to receive them, they will excite the idea of a ftrong lively white. But if the paper be placed farther from the glass, as at r s, the different colours will appear again upon it, in an inverted order, occasioned by the rays croffing at W.

As white is a composition of all colours, fo black is a privation of them all, and, therefore, properly no colour.

Fig. 6.

Let two concentric circles be drawn on a fmooth round board ABCDEFG, and the outermost of them divided into 360 equal parts or degrees: then, draw feven right lines, as O A. O B, &c. from the center to the outermost circle; making the lines \odot A and \odot B include So degrees of that circle; the lines $\odot B$ and $\odot C$ 40 degrees; $\bigcirc C$ and $\bigcirc D$ 60; $\bigcirc D$ and $\bigcirc E$ 60; $\odot E$ and $\odot F_{48}$; $\odot F$ and $\odot G_{27}$; $\odot G$ and $\odot A$ 45. Then, between thefe two circles, paint the fpace AG red, inclining to orange near G; GF orange, inclining to yellow near F; F E yellow, inclining to green near E; ED green, inclining to blue near D; DC blue, inclining to indigo near C; C B indigo, inclining to violet near B; and B A violet, inclining to a foft red near A. This done, paint all that part of the board black which

Of Optics.

which lies within the inner circle; and putting All de an axis through the center of the board, let it prifmatic be turned very fwiftly round that axis, fo as the blended rays proceeding from the above colours, may be together, all blended and mixed together in coming to make a the eye; and then, the whole coloured part will white. appear like a white ring, a little greyifh; not perfectly white, becaufe no colours prepared by art are perfect.

Any of these colours, except red and violet, may be made by mixing together the two contiguous prifmatic colours. Thus, yellow is made by mixing together a due proportion of orange and green; and green may be made by a mixture of yellow and blue.

All bodies appear of that colour, whofe rays they reflect most; as a body appears red when it reflects molt of the red-making rays, and abforbs the reft.

Any two or more colours that are quite tranf- Transpaparent by themfelves, become opake when put rent cotogether. Thus, if water or fpirits of wine be lours betinged red, and put in a phial, every object feen opake if through it will appear red ; because it lets only put tothe red rays pais through it, and ftops all the gether. reft. If water or fpirits be tinged blue, and put in a phial, all objects feen through it will appear blue, becaufe it transmits only the blue rays, and ftops all the reft. But if these two phials are held clofe together, fo as both of them may be between the eye and object, the object will no more be feen through them than through a plate of metal; for whatever rays are transmitted through the fluid in the phial next the object, are flopped by that in the phial next the eye. In this experiment, the phials ought not to be round, but fquare; becaufe nothing but the R 2 light

light itfelf can be feen through a round tranfparent body, at any diffance.

As the rays of light fuffer different degrees of refraction by pafling obliquely through a prifm, or through a convex glafs, and are thereby feparated into all the feven original or primary colours; io they alfo fuffer different degrees of refraction by paffing through drops of falling rain; and then, being reflected towards the eye, from the fides of thefe drops which are fartheft from the eye, and again refracted by paffing out of thefe drops into the air, in which refracted directions they come to the eye; they make all the colours to appear in the form of a fine arch in the heavens, which is called the *rain-bow*.

There are always two rain-bows feen together, the interior of which is formed by the rays a b, which falling upon the upper part b, of the drop b c d, are refracted into the line b c as they enter the drop, and are reflected from the back of it at c, in the line c d, and then, by paffing out of the drop into air, they are again refracted at d; and from thence they pafs on to the eye at e: fo that to form the interior bow, the rays fuffer two refractions, as at b and d; and one reflection, as at c.

The exterior bow is formed by rays which fuffer two reflections, and two refractions; which is the occasion of its being lefs vivid than the interior, and also of its colours being inverted with respect to those of the interior. For, when a ray a b falls upon the lower part of the drop b c d e, it is refracted into the direction b cby entering the drop; and passing on to the back of the drop at c, it is thence reflected in the line c d, in which direction it is impossible for it to enter the eye at f: but by being again reflected

Fig. 8.

Fig. 7.

Of the Terrestrial Globe.

flected from the point d of the drop, it goes on in the drop to e, where it paffes out of the drop into the air, and is there refracted downward to the eye, in the direction ef.

LECT. VIII. AND IX.

The description and use of the globes, and armillary Sphere.

TF a map of the world be accurately delineated The teron a fpherical ball, the furface thereof will refirial represent the furface of the earth : for the higheft globe. hills are fo inconfiderable with refpect to the bulk of the earth, that they take off no more from its roundness, than grains of fand do from the roundness of a common globe; for the diameter of the earth is 8000 miles in round numbers, and no known hill upon it is three miles in perpendicular height.

That the earth is fpherical, or round like a Proof of globe, appears, 1. From its cafting a round the earth's thadow upon the moon whatever fide he turned being fhadow upon the moon, whatever fide be turned globalar. towards her when the is eclipted. 2. From its having been failed round by feveral perfons. 3. From our feeing the farther, the higher we ftand. 4. From our feeing the mafts of a fhip, whilft the hull is hid by the convexity of the water.

The attractive power of the earth draws all it may be terrestrial bodies towards its center; as is evi- peopled dent from the defcent of bodies in lines per- on all fides pendicular to the earth's furface, at the places any one's whereon they fall; even when they are thrown being in off from the earth on opposite fides, and con- danger of fequently, in opposite directions. So that the falling a-

earth it.

247

R 3

earth may be compared to a great magnet rolled in filings of fteel, which attracts and keeps them equally faft to its furface on all fides. Hence, as all terreftrial bodies are attracted toward the earth's center, they can be in no danger of falling from any fide of the earth, more than from any other.

The heaven or fky furrounds the whole earth: and when we fpeak of up or down, we mean only with regard to ourfelves; for no point, either in the heaven, or on the furface of the earth, is above or below, but only with refpect to ourfelves. And let us be upon what part of the earth we will, we ftand with our feet towards its center, and our heads towards the fky: and fo we fay, it is up towards the fky, and down toward the center of the earth.

To an observer placed any where in the indefinite fpace, where there is nothing to limit his view, all remote objects appear equally diftant from him; and feem to be placed in a valt concave fphere, of which his eye is the Every aftronomer can demonstrate, center. that the moon is much nearer to us than the fun is; that fome of the planets are fometimes nearer to us, and fometimes farther from us, than the fun; that others of them never come fo near us as the fun always is; that the remoteft planet in our fystem, is beyond comparison nearer to us than any of the fixed flars are; and that it is highly probable fome ftars are, in a manner, infinitely more diftant from us than others; and yet all these celestial objects appear equally diftant from us. Therefore, if we imagine a large hollow iphere of glafs to have as many bright fluds fixed to its infide, as there are flars visible in the heaven, and these ftuds

Up and down, what.

All objects In the heaven appear equally diftant.

The face of the heaven and earth

ftuds to be of different magnitudes, and placed representat the fame angular diftances from each other ed in a as the ftars are; the fphere will be a true re- machine. prefentation of the ftarry heaven, to an eye fuppofed to be in its center, and viewing it all around. And if a small globe, with a map of the earth upon it, be placed on an axis in the center of this ftarry fphere, and the fphere be made to turn round on this axis, it will reprefent the apparent motion of the heavens round the earth.

If a great circle be fo drawn upon this fphere, as to divide it into two equal parts, or hemifpheres, and the plane of the circle be perpendicular to the axis of the fphere, this circle will represent the equinoEtial, which divides the hea- The equiven into two equal parts, called the northern and notical. the foutbern bemispheres; and every point of that circle will be equally diftant from the poles, or The poles. ends of the axis in the fphere. That pole which is in the middle of the northern hemisphere, will be called the north pole of the fphere, and that which is in the middle of the fouthern hemifphere, the fouth pole.

If another great circle be drawn upon the fphere, in fuch a manner as to cut the equinoctial at an angle of 232 degrees in two opposite points, it will represent the ecliptic, or circle of The eclipthe fun's apparent annual motion : one half of tic. which is on the north fide of the equinoctial, and the other half on the fouth.

If a large flud be made to move eaftward in this ecliptic, in fuch a manner as to go quite round it, in the time that the fphere is turned round westward 366 times upon its axis; this stud will represent the fun, changing his place The fun. every day a 365th part of the ecliptic; and R 4 going

going round weftward, the fame way as the ftars do; but with a motion fo much flower than the motion of the ftars, that they will make 366 revolutions about the axis of the fphere, in the time that the fun makes only 365. During one half of theie revolutions, the fun will be on the north fide of the equinoctial; during the other half, on the fouth : and at the end of each half, in the equinoctial.

Theearth.

The apparent motion of the heavens.

If we suppose the terrestrial globe in this machine to be about one inch in diameter, and the diameter of the ftarry fphere to be about five or fix feet, a fmall infect on the globe would fee only a very little portion of its furface; but it would fee one half of the ftarry fphere; the convexity of the globe hiding the other half from its view. If the fphere be turned weftward round the globe, and the infect could judge of the appearances which arife from that motion, it would fee fome ftars rifing to its view in the eaflern fide of the fphere, whilst others were fetting on . the western : but as all the stars are fixed to the fphere, the fame flars would always rife in the fame points of view on the east fide, and fet in the fame points of view on the weft fide. With the fun it would be otherwife, becaufe the fun is not fixed to any point of the fphere, but moves flowly along an oblique circle in it. And if the infect fhould look towards the fouth, and call that point of the globe, where the equinoctial in the fphere feems to cut it on the left fide, the east point; and where it cuts the globe on the right fide, the west point ; the little animal would fee the fun rife north of the eaft, and fet north of the weft, for 182; revolutions; after which, for as many more, the fun would rife fouth of the east, and fet fouth of the weft.

weft. And in the whole 365 revolutions, the fun would rife only twice in the eaft point, and fet twice in the weft. All these appearances would be the fame, if the ftarry fphere ftood ftill (the fun only moving in the ecliptic) and the earthly globe were turned round the axis of the fphere eastward. For, as the infect would be carried round with the globe, he would be quite infensible of its motion; and the fun and ftars would appear to move westward.

We are but very fmall beings when compared with our earthly globe, and the globe itfelf is but a dimenfionlefs point compared with the magnitude of the flarry heavens. Whether the earth be at reft, and the heaven turns round it, or the heaven be at reft, and the earth turns round, the appearance to us will be exactly the fame. And becaufe the heaven is fo immenfely large, in comparison of the earth, we fee one half of the heaven as well from the earth's furface, as we could do from its center, if the limits of our view are not intercepted by hills.

We may imagine as many circles defcribed Circles of upon the earth as we pleafe; and we may the fphere. imagine the plane of any circle defcribed upon the earth to be continued, until it marks a circle in the concave fphere of the heavens.

The borizon is either fensible or rational. The The borifensible horizon is that circle, which a man ftand-zon. ing upon a large plane, observes to terminate his view all around, where the heaven and earth feem to meet. The plane of our fensible horizon continued to the heaven, divides it into two hemisperes; one visible to us, the other hid by the convexity of the earth.

The

:25I

The plane of the *rational borizon*, is fuppofed parallel to the plane of the fenfible; to pafs through the center of the earth, and to be continued to the heavens. And although the plane of the fenfible horizon touches the earth in the place of the obferver, yet *this* plane, and *that* of the rational horizon, will feem to coincide in the heaven, becaufe the whole earth is but a point compared to the fphere of the heaven.

The earth being a fpherical body, the horizon, or limit of our view, must change as we change our place.

The poles of the earth, are those two points on its furface in which its axis terminates. The one is called the north pole, and the other the fouth pole.

The poles of the beaven, are those two points in which the earth's axis produced terminates in the heaven : fo that the north pole of the heaven is directly over the north pole of the earth ; and the fouth pole of the heaven is directly over the fouth pole of the earth.

Equator.

Poles.

The equator is a great circle upon the earth, every part of which is equally diftant from either of the poles. It divides the earth into two equal parts, called the northern and fouthern hemispheres. If we suppose the plane of this circle to be extended to the heaven, it will mark the equinostial therein, and will divide the heaven into two equal parts, called the northern and fouthern hemispheres of the heaven.

Meridian.

The meridian of any place is a great circle paffing through that place and the poles of the earth. We may imagine as many fuch meridians as we pleafe, becaufe any place that is ever

ever to little to the eaft or weft of any other place, has a different meridian from that place; for no one circle can pais through any two fuch places and the poles of the earth.

The meridian of any place is divided by the poles, into two femicircles : that which paffes through the place is called the geographical, or upper meridian; and that which paffes through the opposite place, is called the lower meridian.

When the rotation of the earth brings the Noon and plane of the geographical meridian to the fun, mid-night. it is noon or mid-day to that place; and when our lower meridian comes to the fun, it is midnight.

All places lying under the fame geographical meridian, have their noon at the fame time, and confequently all the other hours. All those places are faid to have the fame longitude, becaufe no one of them lies either eaftward or weltward from any of the reft.

If we imagine 24 femicircles, one of which Hour citis the geographical meridian of a given place, cles, to meet at the poles, and to divide the equator into 24 equal parts; each of thefe meridians will come round to the fun in 24 hours, by the earth's equable motion round its axis in that time. And, as the equator contains 360 degrees, there will be 15 degrees contained between any two of these meridians which are nearest to one another: for 24 times 15 is 360. And as the earth's motion is eaftward, the fun's apparent motion will be weftward, at the rate of 15 degrees each hour. Therefore,

They whole geographical meridian is 15 de- Longitude. grees eaftward from us, have noon, and every other hour, an hour fooner than we have. They whofe meridian is fifteen degrees weftward from us.

us, have noon, and every other hour, an hour later than we have: and fo on in proportion, reckoning one hour for every fifteen degrees.

As the earth turns round its axis once in 24 hours, and fnews itfelf all round to the fun in that time; fo it goes round the fun once a year, in a great circle called the ecliptic, which croffes the equinoctial in two opposite points, making an angle of 232 degrees with the equinoctial on each fide. So that one half of the ecliptic is in the northern hemisphere, and the other in the fouthern. It contains 360 equal parts, called degrees (as all other circles do, whether great or fmall) and as the earth goes once round it every year, the fun will appear to do the fame, changing his place almost a degree, at a mean rate, every 24 hours. So that whatever place, or degree of the ecliptic, the earth is in at any time, the fun will then appear in the opposite. And as one half of the ecliptic is on the north fide of the equinoctial, and the other half on the fouth ; the fun, as feen from the earth, will be half a year on the fouth fide of the equinoctial, and half a year on the north : and twice a year in the equinoctial itfelf.

Signs and degrees.

The ecliptic is divided by aftronomers into 12 equal parts, called *figns*, each fign into 30 *degrees*, and each degree into 60 *minutes*: but in ufing the globes, we feldom want the fun's place nearer than half a degree of the truth.

The names and characters of the 12 figns are as follow; beginning at that point of the ecliptic where it croffes the equinoctial to the northward, and reckoning eattward round to the fame point again. And the days of the months on which the fun now enters the figns, are fet down below them.

By remembering on what day the fun enters any particular fign, we may eafily find his place any day afterward, whilft he is in that fign, by reckoning a degree for each day; which will occafion no error of confequence in using the globes.

When the fun is at the beginning of Aries, he is in the equinoctial; and from that time he declines northward every day, until he comes to the beginning of *Cancer*, which is $23\frac{1}{2}$ degrees from the equinoctial: from thence he recedes fouthward every day, for half a year; in the middle of which half, he croffes the equinoctial at the beginning of *Libra*, and at the end of that half year, he is at his greateft fouth declination, in the beginning of *Capricorn*, which is alfo $23\frac{1}{2}$ degrees from the equinoctial. Then, he returns northward from *Capricorn* every day, for half a year; in the middle of which half, he croffes the equinoctial at the beginning of *Aries*; and at the end of it he arrives at *Cancer*. 255

The

The fun's motion in the ecliptic is not perfectly equable, for he continues eight days longer in the northern half of the ecliptic, than in the fouthern: fo that the fummer half year, in the northern hemifphere, is eight days longer than the winter half year; and the contrary in the fouthern hemifphere.

Tropics.

The tropics are leffer circles in the heaven, parallel to the equinoctial; one on each fide of it, touching the ecliptic in the points of its greateft declination; fo that each tropic is $23\frac{1}{2}$ degrees from the equinoctial, one on the north fide of it, and the other on the fouth. The northern tropic touches the ecliptic at the beginning of *Cancer*, the fouthern at the beginning of *Capricorn*; for which reafon the former is called the *tropic of Cancer*, and the latter the *tropic of Capricorn*.

Polar circles.

The polar circles in the heaven, are each $23\frac{1}{2}$ degrees from the poles, all around. That which goes round the north pole, is called the artic circle, from 2eil@, which fignifies a bear; there being a collection or groupe of flars near the north pole, which goes by that name. The fouth polar circle, is called the antartic circle, from its being opposite to the arctic.

The ecliptic, tropics, and polar circles, are drawn upon the terreftrial globe, as well as upon the celeftial. But the ecliptic, being a great fixed circle in the heavens, cannot properly be faid to belong to the terreftrial globe; and is laid down upon it only for the conveniency of folving fome problems. So that, if this circle on the terreftrial globe was properly divided into the months and days of the year, it would not only fuit the globe better, but would alfo make the problems thereon much eafier.

In

In order to form a true idea of the earth's motion round its axis every 24 hours, which is the caufe of day and night; and of its motion in the ecliptic round the fun every year, which is the caufe of the different lengths of days and nights, and of the vicifitude of feafons; take the following method, which will be both eafy and pleafant.

Let a fmall terreftrial globe, of about three An idea inches diameter, be fuspended by a long thread of the of twifted filk, fixt to its north pole : then hav- featons. ing placed a lighted candle on a table, to reprefent the fun, in the center of a hoop of a large cafk, which may reprefent the ecliptic, the hoop making an angle of 232 degrees with the plane of the table; hang the globe within the hoop near to it; and if the table be level, the equator of the globe will be parallel to the table, and the plane of the hoop will cut the equator at an angle of $23\frac{3}{2}$ degrees; fo that one half of the equator will be above the hoop, and the other half below it: and the candle will enlighten one half of the globe, as the fun enlightens one half of the earth, whilft the other half is in the dark.

Things being thus prepared, twift the thread towards the left hand, that it may turn the globe the fame way by untwifting; that is, from weft, by fouth, to eaft. As the globe turns round its axis or thread, the different places of its furface will go regularly through the light and dark; and have, as it were, an alternate return of day and night in each rotation. As the globe continues to turn round, and to fhew itfelf all around to the candle, carry it flowly round the hoop by the thread, from weft, by fouth, to eaft; which is the way that the earth moves

moves round the fun, once a year, in the ecliptic : and you will fee, that whilft the globe continues in the lower part of the hoop, the candle (being then north of the equator) will conftantly fhine round the north pole; and all the northern places which go through any part of the dark, will go through a lefs portion of it than they do of the light; and the more fo, the farther they are from the equator: confequently, their days are then longer than their nights. When the globe comes to a point in the hoop, mid-way between the higheft and loweft points, the candle will be directly over the equator, and will enlighten the globe just from pole to pole ; and then every place on the globe will go through equal portions of light and darkness, as it runs round its axis; and confequently, the day and night will be of equal length at all places upan it. As the globe advances thenceforward, towards the highest part of the hoop, the candle will be on the fouth fide of the equator, fhining farther and farther round the fouth pole, as the globe rifes higher and higher in the hoop; leaving the north pole as much in darkneis, as the fourth pole is then in the light, and making long days and fhort nights on the fouth fide of the equator, and the contrary on the north fide, whilft the globe continues in the nothern or higher fide of the hoop : and when it comes to the highest point, the days will be at the longest, and the nights at the shortest, in the fouthern hemisphere; and the reverse in the northern. As the globe advances and defcends in the hoop, the light will gradually recede from the fouth pole, and approach towards the north pole, which will caufe the northern days to lengthen, and the fouthern days to shorten in the 3

the fame proportion. When the globe comes to the middle point, between the higheft and loweft points of the hoop, the candle will be over the equator, enlightening the globe juft from pole to pole, when every place of the earth (except the poles) will go through equal portions of light and darknefs; and confequently, the day and night will be then equal, all over the globe.

And thus, at a very fmall expence, one may have a delightful and demonstrative view of the caufe of days and nights, with their gradual increase and decrease in length, through the whole year together, with the vicifitudes of fpring, fummer, autumn, and winter, in each annual course of the earth round the fun.

If the hoop be divided into 12 equal parts, and the figns be marked in order upon it, beginning with Cancer at the highest point of the hoop, and reckoning eaftward (or contrary to the apparent motion of the fun) you will fee how the fun appears to change his place every day in the ecliptic, as the globe advances eaftward along the hoop, and turns round its own axis: and that when the earth is in a low fign, as at Capricorn, the fun must appear in a high fign, as at Cancer, opposite to the earth's real place: and that whill the earth is in the fouthern half of the ecliptic, the fun appears in the northern half, and vice verfa : that the farther any place is from the equator, between it and the polar circle, the greater is the difference between the longest and thortest day at that place; and that the poles have but one day and one night in the whole year.

These things premised, we shall proceed to the description and use of the terrestrial globe, S and

The Terrestrial Globe described.

and explain the geographical terms as they occur in the problems.

The terrestrial globe defcribed. This globe has the boundaries of land and water laid down upon it, the countries and kingdoms divided by dots, and coloured to diftinguish them, the islands properly fituated, the rivers and principal towns inferted, as they have been afcertained upon the earth by meafurement and observation.

The equator, ecliptic, tropics, polar circles, and meridians, are laid down upon the globe in the manner already defcribed. The ecliptic is divided into 12 figns, and each fign into 30 degrees, which are generally fubdivided into halves, and into quarters if the globe is large. Each tropic is 231 degrees from the equator, and each polar circle 231 degrees from its respective pole. Circles are drawn parallel to the equator, at every ten degrees diffance from it on each fide to the poles : these circles are called parallels of latitude. On large globes there are circles drawn perpendicularly through every tenth degree of the equator, interfecting each other at the poles : but on globes of or under a foot diameter, they are only drawn through every fifteenth degree of the equator : thefe circles are generally called meridians, fometimes circles of longitude, and at other times bourcircles.

The globe is hung in a brafs ring, called the brafen meridian; and turns upon a wire in each pole funk half its thicknefs into one fide of the meridian ring; by which means, that fide of the ring divides the globe into two equal parts, called the eaftern and western hemispheres; as the equator divides it into two equal parts, called the worthern and southern hemispheres. This ring is 4

The Terrestrial Globe described.

divided into 360 equal parts or degrees, on the fide wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned, from the equator to the poles, where they end at 90: their use is to shew the latitudes of places. The degrees on the other half of the meridian ring, are numbered from the poles to the equator, where they end at 90: their use is to fhew how to elevate either the north or fouth pole above the horizon, according to the latitude of any given place, as it is north or fouth of the equator.

The brafen meridian is let into two notches made in a broad flat ring, called the wooden horizon, the upper furface of which divides the globe into two equal parts, called the upper and lower bemispheres. One notch is in the north point of the horizon, and the other in the fourh. On this horizon are feveral concentric circles, which contain the months and days of the year, the figns and degrees answering to the fun's place for each month and day, and the 32 points of the compais .- The graduated fide of the brafs meridian lies towards the east fide of the horizon, and should be generally kept toward the perfon who works problems by the globes.

There is a fmall borary circle, fo fixed to the north part of the brafen meridian, that the wire in the north pole of the globe is in the center of that circle; and on the wire is an index, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brafen meridian ; which is the contrivance of the late ingenious Mr. Joseph Harris, master of the affay-office in the Tower of London; and makes it very conve-S 2 nient

The Terrestrial Globe described.

nient for putting the poles of the globe through the horizon, and for elevating the pole to fmall latitudes, and declinations of the fun ; which cannot be done where there is only one horary circle fixed to the outer edge of the brafen meridian.

There is a thin flip of brafs, called the quadrant of altitude, which is divided into 90 equal parts or degrees, anfwering exactly to fo many degrees of the equator. It is occasionally fixed to the uppermost point of the brafen meridian by a nut and fcrew. The divisions end at the nut, and the quadrant is turned round upon it.

As the globe has been feen by most people, and upon the figure of which, in a plate, neither the circles nor countries can be properly expressed, we judge it would fignify very little to refer to a figure of it; and shall therefore only give fome directions how to choose a globe. and then defcribe its ufe.

Directions ing of globes.

1. See that the papers be well and neatly for choof- pafted on the globes, which you may know, if the lines and circles thereon meet exactly, and continue all the way even and whole; the circles not breaking into feveral arches, nor the papers either coming fhort, or lapping over one another.

2. See that the colours be transparent, and not laid too thick upon the globe to hide the names of places.

3. See that the globe hang evenly between the brafen meridian and the wooden horizon; not inclining either to one fide or to the other.

4. See that the globe be as close to the horizon and meridian as it conveniently may; otherwife, you will be too much puzzled to find againit

Directions for choosing Globes.

against what part of the globe any degree of the meridian or horizon is.

5. See that the equinoctial line be even with the horizon all around, with the north or fouth pole is elevated 90 degrees above the horizon.

6. See that the equinoctial line cuts the horizon in the east and west points, in all elevations of the pole from o to go degrees.

7. See that the degree of the brafen meridian marked with o, be exactly over the equinoctial line of the globe.

8. See that there be exactly half of the brafen meridian above the horizon; which you may know, if you bring any of the decimal divisions on the meridian to the north point of the horizon, and find their complement to go in the fouth point.

9. See that when the quadrant of altitude is placed as far from the equator, on the brafen meridian, as the pole is elevated above the horizon, the beginning of the degrees of the quadrant reaches just to the plane furface of the horizon.

10. See that whilft the index of the hourcircle (by the motion of the globe) paffes from one hour to another, 15 degrees of, the equator pass under the graduated edge of the brasen meridian.

11. See that the wooden horizon be made fubftantial and ftrong: it being generally obferved, that in most globes, the horizon is the first part that fails, on account of its having been made too flight.

In using the globes, keep the east fide of the Directions horizon towards you (unlefs your problem re- for using quires the turning of it) which fide you may them. know by the word East upon the horizon ; for

then

S 3

then you have the graduated fide of the meridian towards you, the quadrant of altitude before you, and the globle divided exactly into two equal parts, by the graduated fide of the meridian.

In working fome problems, it will be neceffary to turn the whole globe and horizon about, that you may look on the weft fide thereof; which turning will be apt to jog the ball fo, as to fhift away that degree of the globe which was before let to the horizon or meridian: to avoid which inconvenience, you may thruft in the feather-end of a quill between the ball of the globe and the brafen meridian; which, without hurting the ball, will keep it from turning in the meridian, whilft you turn the weft fide of the horizon towards you.

PROBLEM I.

To find the * latitude and + longitude of any given place upon the globe.

Turn the globe on its axis, until the given place comes exactly under that graduated fide of the brafen meridian, on which the degrees are numbered

* The latitude of a place is its diffance from the equator, and is north or fouth, as the place is north or fouth of the equator. Those who live at the equator have no latitude, because it is there that the latitude begins.

† The longitude of a place is the number of degrees (reckoned upon the equator) that the meridian of the faid place is diffant from the meridian of any other place from which we reckon, either eaflward or weftward, for 180 degrees, or half round the globe. The British reckon the longitude from the meridian of London, and the French now reckon it from the meridian of Paris. The meridian of that place, from which the longitude is reckoned, is called

numbered from the equator; and obferve what degree of the meridian the place then lies under; which is its latitude, north or fouth, as the place is north or fouth of the equator.

The globe remaining in this polition, the degree of the equator, which is under the brafen meridian, is the longitude of the place, (from the meridian of *London* on the *Englifb* globes) which is eaft or weft, as the place lies on the eaft or weft fide of the firft meridian of the globe.—All the *Atlantic Ocean*, and *America*, is on the weft fide of the meridian of *London*; and the greateft part of *Europe*, and of *Africa*, together with all *Afia*, is on the eaft fide of the meridian of *London*, which is reckoned the *firft meridian* of the globe by the *Britifb* geographers and aftronomers.

PROBLEM II.

The longitude and latitude of a place being given, to find that place on the globe.

Look for the given longitude in the equator (counting it eaftward or weftward from the firft meridian, as it is mentioned to be eaft or weft;) and bring the point of longtude in the equator to the brafen meridian, on that fide which is above the fouth point of the horizon: then count from the equator, on the brafen meridian, to the degree of the given latitude, towards the north or fouth pole, according as the latitude is north or fouth; and under that degree of latitude on the meridian, you will have the place required.

called the *first meridian*. The places upon this meridian have no longitude, because it is there that the longitude begins.

S 4

PROB-

PROBLEM III.

To find the difference of longitude, or difference of latitude, between any two given places.

Bring each of these places to the brasen meridian, and see what its latitude is: the leffer latitude subtracted from the greater, if both places are on the same fide of the equator, or both latitudes added together, if they are on different fides of it, is the difference of latitude required. And the number of degrees contained between these places, reckoned on the equator, when they are brought separately under the brasen meridian, is their difference of longitude; if it be less than 180: but if more, let it be subtracted from 360, and the remainder is the difference of longitude required. Or,

Having brought one of the places to the brafen meridian, and fet the hour-index to XII, turn the globe until the other place comes to the brafen meridian, and the number of hours and parts of an hour, paft over by the index, will give the longitude in time; which may be eafily reduced to degrees, by allowing 15 degrees for every hour, and one degree for every four minutes.

N. B. When we fpeak of bringing any place to the brafen meridian, it is the graduated fide of the meridian that is meant.

266

PROB-

PROBLEM IV.

Any place being given, to find all those places that have the same longitude or latitude with it.

Bring the given place to the brafen meridian, then all those places which lie under that fide of the meridian, from pole to pole, have the fame longitude with the given place. Turn the globe round its axis, and all those places which pass under the fame degree of the meridian that the given place does, have the fame latitude with that place.

Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the firft meridian, it is evident, that the point of the equator which is cut by the firft meridian, has neither latitude nor longitude.—The greateft latitude is 90 degrees, becaufe no place is more than 90 degrees from the equator. And the greateft longitude is 180 degrees, becaufe no place is more than 180 degrees from the firft meridian.

PROBLEM V.

To find the * antœci, ‡ periœci, and ‡ antipodes, of any given place.

Bring the given place to the brafen meridian, and having found its latitude, keep the globe in that fituation, and count the fame number of degrees

• The antaci are those people who live on the fame meridian, and in equal latitudes, on different fides of the equator. Being on the fame meridian, they have the fame hours ; that is, when it is noon to the one, it is also noon to the other; and when it is mid-night to the one, it is also midnight to the other, &c. Being on different fides of the equator

degrees of latitude from the equator towards the contrary pole, and where the reckoning ends, you have the *antaci* of the given place upon the globe. Those who live at the equator have no *antaci*.

The globe remaining in the fame position, fet the hour-index to the upper XII. on the horary circle, and turn the globe until the index comes to the lower XII; then, the place which lies under the meridian, in the fame latitude with the given place, is the *periæci* required. Those who live at the poles have no *periæci*.

As the globe now ftands (with the index at the lower XII.) the *antipodes* of the given place will be under the fame point of the brafen meridian where its *antaci* ftood before. Every place upon the globe has its *antipodes*.

tor, they have different or opposite feasons at the fame time; the length of any day to the one is equal to the length of the night of that day to the other; and they have equal elevations of the different poles.

+ The perizei are those people who live on the fame parallel of latitude, but on opposite meridians: so that though their latitude be the fame, their longitude differs 180 degrees. By being in the fame latitude, they have equal elevations of the fame pole (for the elevation of the pole is always equal to the latitude of the place) the fame length of days or nights, and the fame feasors. But being on oppofite meridians, when it is noon to the one, it is mid-night to the other.

[†] The antipodes are those who live diametrically oppofite to one another upon the globe, flanding with feet towards feet, on opposite meridians and parallels. Being on opposite fides of the equator, they have opposite featons, winter to one, when it is fummer to the other; being equally distant from the equator, they have their contrary poles equally elevated above the horizon; being on opposite meridians, when it is noon to the one, it must be mid-night to the other; and as the four recedes from the one when he approaches to the other, the length of the day to one must be equal to the length of the night at the fame time to the other.

PROB.

PROBLEM VI.

To find the distance between any two places on the globe.

Lay the graduated edge of the quadrant of altitude over both the places, and count the number of degrees intercepted between them on the quadrant; then multiply thefe degrees by 60, and the product will give the diftance in geographical miles: but to find the diftance in Englifh miles, multiply the degrees by $69\frac{1}{2}$, and the product will by the number of miles required. Or, take the diftance betwixt any two places with a pair of compaffes, and apply that extent to the equator; the number of degrees, intercepted between the points of the compaffes, is the diftance in degrees of a great circle *; which may be reduced either to geographical miles, or to Englifh miles, as above.

* Any circle that divides the globe into two equal parts, Great is called a great circle, as the equator or meridian. Any circle. circle that divides the globe into two unequal parts (which every parallel of latitude does) is called a leffer circle. Now, Leffer as every circle, whether great or fmall, contains 360 degrees, circle, and a degree upon the equator or meridian contains 60 geographical miles, it is evident, that a degree of longitude upon the equator, is longer than a degree of longitude upon any parallel of latitude, and must therefore contain a greater number of miles. So that, although all the degrees of latitude are equally long upon an artificial globe (though not precifely fo upon the earth itfelf) yet the degrees of longitude decrease in length, as the latitude increases, but not in the fame proportion. The following table fhews the length of a degree of longitude, in geographical miles, and hundredth parts of a mile, for every degree of latitude, from the equator to the poles : a degree on the equator being 60 geographical miles.

PROB-
PROBLEM VII.

A place on the globe being given, and its distance from any other place, to find all the other places upon the globe which are at the same distance from the given place.

Bring the given place to the brafen meridian, and fcrew the quadrant of altitude to the meridian, directly over that place; then keeping the globe in that polition, turn the quadrant quite round upon it, and the degree of the quadrant that touches the fecond place, will pass over all the other places which are equally diftant with it from the given place.

This is the fame as if one foot of a pair of compafies was fet in the given place, and the other foot extended to the fecond place, whofe diftance is known; for if the compafies be then turned round the first place as a center, the moving foot will go over all those places which are at the fame diftance with the fecond from it.

the equator, is larger than a signerative types in a re-

and the strategical bound and the state of the second

ATABLE shewing the number of miles in a degree of longitude, in any given degree of latitude.

PROB.

PROBLEM VIII.

The hour of the day at any place being given, to find all those places where it is noon at that time.

Bring the given place to the brafen meridian, and fet the index to the given hour; this done, turn the globe until the index points to the upper XII, and then, all the places that lie under the brafen meridian have noon at that time.

N. B. The upper XII always ftands for noon; and when the bringing of any place to the brafen meridian is mentioned, the fide of that meridian on which the degrees are reckoned from the equator is meant, unlefs the contrary fide be mentioned.

PROBLEM IX.

The hour of the day at any place being given to find what o'clock it then is at any other place.

Bring the given place to the brafen meridian, and fet the index to the given hour; then turn the globe, until the place where the hour is required comes to the brafen meridian, and the index will point out the hour at that place.

PROBLEM X.

To find the fun's place in the ecliptic, and his * declination, for any given day of the year.

Look on the horizon for the given day, and right against it you have the degree of the fign in which the fun is (or his place) on that day

* The fun's declination is his diffance from the equinodial in degrees, and is north or fouth, as the fun is between the equinodial and the north or fouth pole.

at

at noon. Find the fame degree of that fign in the ecliptic line upon the globe, and having brought it to the brafen meridian, obferve what degree of the meridian ftands over it; for that is the fun's declination, reckoned from the equator.

PROBLEM XI.

The day of the month being given, to find all those places of the earth over which the fun will pass vertically on that day.

Find the fun's place in the ecliptic for the given day, and having brought it to the brafen meridian, obferve what point of the meridian is over it; then turning the globe round its axis; all those places which pass under that point of the meridian are the places required; for as their latitude is equal, in degrees and parts of a degree, to the fun's declination, the fun must be directly over head to each of them at its respective noon.

PROBLEM XII.

A place being given in the* torrid zone, to find those two days of the year, on which the fun shall be vertical to that place.

Bring the given place to the brafen meridian, and mark the degree of latitude that is exactly over

* The globe is divided into five zones ; one torrid, two temperate, and two feigid. The torrid zone lies between the two tropics, and is 47 degrees in breadth, or $23\frac{1}{2}$ on each fide of the equator : the temperate zones lie between the tropics and polar circles, or from $23\frac{1}{2}$ degrees of latitude, to $66\frac{1}{2}$, on each

over it on the meridian; then turn the globe round its axis, and obferve the two degrees of the ecliptic which pafs exactly under that degree of latitude: Laftly, find on the wooden horizon the two days of the year on which the fun is in those degrees of the ecliptic, and they are the days required: for on them, and none elfe, the fun's declination is equal to the latitude of the given place; and confequently, he will then be vertical to it at noon.

PROBLEM XIII.

To find all those places of the north frigid zone, where the fun begins to shine constantly without setting, on any given day, from the 20th of March, to the 23d of September.

On thefe two days, the fun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and fo make the day and night equal to all places of the earth. But as the fun declines from the equator, towards either pole, he will fhine juft as many degrees round that pole, as are equal to his declination from the equator; fo that no place within that diffance of the pole will then go through any part of the dark, and confequently the fun will not fet to it. Now, as

each fide of the equator; and are each 43 degrees in breadth: the *frigid zones* are the fpaces included within the polar circles, which being each $23\frac{1}{2}$ degrees from their refpective poles, the breadth of each of thefe zones is 47 degrees. As the fun never goes without the tropics, he must every moment be vertical to fome place or other in the torrid zone.

6

the

the fun's declination is northward, from the 21ft of March to the 23d of September, he muft conftantly fhine round the north pole all that time; and on the day that he is in the northern tropic, he fhines upon the whole north frigid zone; fo that no place within the north polar circle goes through any part of the dark on that day. Therefore,

Having brought the fun's place for the given day to the brafen meridian, and found his declination (by Prob. IX.) count as many degrees on the meridian, from the north pole, as are equal to the fun's declination from the equator, and mark that degree from the pole where the reckoning ends: then, turning the globe round its axis, obferve what places in the north frigid zone pass directly under that mark; for they are the places required.

The like may be done for the fouth frigid zone, from the 23d of September to the 21ft of March, during which time the fun fhines conftantly on the fouth pole.

PROBLEM XIV.

To find the place over which the fun is vertical, at any hour of a given day.

Having found the fun's declination for the given day (by Prob. 1X.) mark it with a chalk on the brafen meridian: then bring the place where you are (fuppofe London) to the brafen meridian, and fet the index to the given hour; which done, turn the globe on its axis, until the index points to XII at noon; and the place on the globe, which is then directly under the point

of

of the fun's declination marked upon the meridian, has the fun that moment in the zenith, or directly overhead.

PROBLEM XV.

The day and hour at any place being given, to find all those places where the sun is then rising, or setting, or on the meridian : consequently, all those places which are enlightened at that time, and those which are in the dark.

This problem cannot be folved by any globe fitted up in the common way, with the hour circle fixed upon the brafs meridian; unlefs the fun be on or near fome of the tropics on the given day. But by a globe fitted up according to Mr. Jofeph Harris's invention (already mentioned) where the hour-circle lies on the furface of the globe, below the meridian, it may be folved for, any day in the year, according to his method; which is as follows.

Having found the place to which the fun is vertical at the given hour, if the place be in the northern hemisphere, elevate the north pole as many degrees above the horizon, as are equal to the latitude of that place; if the place be in the fouthern hemisphere, elevate the fouth pole accordingly; and bring the faid place to the brafen meridian. Then, all those places which are in the western femicircle of the horizon, have the fun rifing to them at that time; and those in the eaftern femicircle have it fetting : to those under the upper femicircle of the brafs meridian, it is noon; and to those under the lower semicircle, it is midnight. All those places which are above the horizon, are enlightened by the fun, and

and have the fun juft as many degrees high to them, as they themfelves are above the horizon : and this height may be known, by fixing the quadrant of altitude on the brafen meridian over the place to which the fun is vertical ; and then, laying it over any other place, obferve what number of degrees on the quadrant are intercepted between the faid place and the horizon. In all those places that are 18 degrees below the western femicircle of the horizon, the morning twilight is just beginning ; in all those places that are 18 degrees below the eastern femicircle of the horizon, the evening twilight is ending ; and all those places that are lower than 18 degrees, have dark night.

If any place be brought to the upper femicircle of the brafen meridian, and the hour index be fet to the upper XII or noon, and then the globe be turned round eaftward on its axis; when the place comes to the weftern femicircle of the horizon, the index will flew the time of fun-rifing at that place; and when the fame place comes to the eaftern femicircle of the horizon, the index will flew the time of fun-fet.

To those places which do not go under the horizon, the fun fets not on that day: and to those which do not come above it, the fun does not rife.

PROBLEM XVI.

The day and hour of a lunar eclipse being given; to find all those places of the earth to which it will be visible.

The moon is never eclipfed but when the is full, and to directly opposite to the fun, that the T_2 earth's

earth's fhadow falls upon her. Therefore, whatever place of the earth the fun is vertical to at that time, the moon muft be vertical to the antipodes of that place : fo that the fun will be then visible to one half of the earth, and the moon to the other.

Find the place to which the fun is vertical at the given hour (by Prob. XIV.) elevate the pole to the latitude of that place, and bring the place to the upper part of the brafen meridian, as in the former problem: then, as the fun will be visible to all those parts of the globe which are above the horizon, the moon will be visible to all those parts of the globe which are below it, at the time of her greatest obscuration.

But with regard to an eclipfe of the fun, there is no fuch thing as fhewing to what places it will be vifible, with any degree of certainty, by a common globe; becaufe the moon's fhadow covers but a fmall portion of the earth's furface; and her latitude, or declination from the ecliptic, throws her fhadow fo varioufly upon the earth, that to determine the places on which it falls, recourfe muft be had to long calculations.

PROBLEM XVII.

To restify the globe for the latitude, the * zenith, and the fun's place.

Find the latitude of the place (by Prob. I.) and if the place be in the northern hemifphere, raife the north pole above the north point of the horizon,

* The zenith, in this fenfe, is the higheft point of the brafen meridian above the horizon; but in the proper fenfe it is that point of the heaven which is directly vertical to any given place, at any given inftant of time.

25

as many degrees (counted from the pole upon the brafen meridian) as are equal to the latitude of the place. If the place be in the fouthern hemifphere, raife the fouth pole above the fouth point of the horizon, as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the brafen meridian, and fasten the quadrant of altitude fo, that the chamfered edge of its nut (which is even with the graduated edge) may be joined to the zenith, or point of latitude. This done, bring the fun's place in the ecliptic for the given day, (found by Prob. X.) to the graduated fide of the brasen meridian, and set the hour-index to XII. at noon, which is the uppermoft XII on the hour-circle; and the globe will be rectified.

The latitude of any place is equal to the ele- Remark, vation of the nearest pole of the heaven above the horizon of that place; and the poles of the heaven are directly over the poles of the earth, each 90 degrees from the equinoctial line. Let us be upon what place of the earth we will, if the limits of our view be not intercepted by hills, we shall see one half of the heaven, or 90 degrees every way round, from that point which is over our heads. Therefore. if we were upon the equator, the poles of the heaven would lie in our horizon, or limit of our view : if we go from the equator, towards either pole of the earth, we shall see the corresponding pole of the heaven rifing gradually above our horizon, just as many degrees as we have gone from the equator : and if we were at either of the earth's poles, the corresponding pole of the heaven would be directly over our head. Confequently, the elevation or height of the pole in T 3 degrees

degrees above the horizon, is equal to the number of degrees that the place is from the equator.

PROBLEM XVIII.

The latitude of any place, not exceeding *66[±]/₂ degrees, and the day of the month, being given; to find the time of fun-rifing and fetting, and confequently the length of the day and night.

Having rectified the globe for the latitude, and for the fun's place on the given day (as directed in the preceding problem) bring the fun's place in the ecliptic to the eaftern fide of the horizon, and the hour-index will fhew the time of fun-rifing; then turn the globe on its axis, until the fun's place comes to the weftern fide of the horizon, and the index will fhew the time of funfetting.

The hour of fun-fetting doubled, gives the length of the day; and the hour of fun-rifing doubled gives the length of the night.

PROBLEM XIX.

The latitude of any place, and the day of the month, being given; to find when the morning twilight begins, and the evening twilight ends, at that place.

This ploblem is often limited; for, when the fun does not go 18 degrees below the horizon, the twilight continues the whole night; and for

* All places whole latitude is more than $66\frac{1}{2}$ degrees, are in the frigid zones: and to thole places the fun does not fet in fummer, for a certain number of diurnal revolutions, which occasions this limitation of latitude.

feveral

feveral nights together in fummer, between 49 and $66\frac{1}{2}$ degrees of latitude: and the nearer to $66\frac{1}{2}$, the greater is the number of these nights. But when it does begin and end, the following method will shew the time for any given day.

Rectify the globe, and bring the fun's place in the ecliptic to the eaftern fide of the horizon; then mark that point of the ecliptic with a chalk which is in the weftern fide of the horizon, it being the point oppofite to the fun's place : this done, lay the quadrant of altitude over the faid point, and turn the globe eaftward, keeping the quadrant at the chalk-mark, until it is just 18 degrees high on the quadrant; and the index will point out the time when the morning twilight begins : for the fun's place will then be 18 degrees below the eaftern fide of the horizon. To find the time when the evening twilight ends, bring the fun's place to the western fide of the horizon, and the point oppofite to it, which was marked with the chalk, will be rifing in the eaft : then, bring the quadrant over that point, and keeping it thereon, turn the globe westward, until the faid point be 18 degrees above the horizon on the quadrant, and the index will fhew the time when the evening twilight ends; the fun's place being then 18 degrees below the weftern fide of the horizon.

T 4

PRO-

PROBLEM XX.

To find on what day of the year the fun begins to fhine constantly without fetting, on any given place in the north frigid zone; and how long he continues to do so.

Rectify the globe to the latitude of the place, and turn it about until fome point of the ecliptic, between Aries and Cancer, coincides with the north point of the horizon where the brafen meridian cuts it : then find, on the wooden horizon, what day of the year the fun is in that point of the ecliptic; for that is the day on which the fun begins to fhine conftantly on the given place, without fetting. This done, turn the globe until fome point of the ecliptic, between Cancer and Libra, coincides with the north point of the horizon, where the brafen meridian cuts it; and find, on the wooden horizon, on what day the fun is in that point of the ecliptic; which is the day that the fun leaves off conftantly fhining on the faid place, and rifes and fets to it as to other places on the globe. The number of natural days, or complete revolutions of the fun about the earth, between the two days above found, is the time that the fun keeps conftantly above the horizon without fetting : for all the portion of the ecliptic, that lies between the two points which interfect the horizon in the very north, never fets below it : and there is just as much of the opposite part of the ecliptic that never rifes; therefore, the fun will keep as long conftantly below the horizon in winter, as above it in fummer.

2

Whoever

Whoever confiders the globe, will find, that all places of the earth do equally enjoy the benefit of the fun, in refpect of time, and are equally deprived of it. For, the days and nights are always equally long at the equator: and in all places that have latitude, the days at one time of the year are exactly equal to the nights at the oppofite feafon.

PROBLEM XXI.

To find in what latitude the fun shines constantly without setting, for any length of time less than * $182\frac{1}{2}$ of our days and nights.

Find a point in the ecliptic half as many degrees from the beginning of *Cancer* (either towards *Aries* or *Libra*) as there are + natural days in the time given; and bring that point to the north fide of the brafen meridian, on which the degrees are numbered from the pole towards the equator: then, keep the globe from turning on its axis, and flide the meridian up or down, until the forefaid point of the ecliptic comes to the north point of the horizon, and then, the elevation of the pole will be equal to the latitude required.

* The reafon of this limitation is, that $18z_2^{1}$ of our days and nights make half a year, which is the longest time that the fun fhines without setting, even at the poles of the earth.

+ A natural day contains the whole 24 hours: an artificial day, the time that the fun is above the horizon,

PRO-

PROBLEM XXII.

The latitude of a place, not exceeding $66\frac{1}{2}$ degrees, and the day, of the month being given; to find the fun's amplitude, or point of the compass on which he rifes or fets on that day.

Rectify the globe, and bring the fun's place to the caftern fide of the horizon; then obferve what point of the compafs on the horizon flands right against the fun's place, for that is his amplitude at rifing. This done, turn the globe weftward, until the fun's place comes to the weftern fide of the horizon, and it will cut the point of his amplitude at fetting. Or, you may count the rifing amplitude in degrees, from the east point of the horizon, to that point where the fun's place cuts it; and the fetting amplitude, from the west point of the horizon, to the fun's place at fetting.

PROBLEM XXIII.

The latitude, the fun's place, and his* altitude, being given; to find the hour of the day, and the fun's azimuth, or number of degrees that he is diftant from the meridian.

Rectify the globe, and bring the fun's place to the given height upon the quadrant of altitude; on the eaftern fide of the horizon, if the time be in the forenoon; or the western fide, if

* The fun's altitude, at any time, is his height in degrees above the horizon at that time,

ic

it be in the afternoon: then, the index will fhew the hour; and the number of degrees in the horizon intercepted between the quadrant of altitude and the fouth point, will be the fun's true azimuth at that time.

N. B. Always when the quadrant of altitude is mentioned in working any problem, the graduated edge of it is meant.

If this be done at fea, and compared with the fun's azimuth, as fhewn by the compafs, if they agree, the compafs has no variation in that place : but if they differ, the compafs does vary ; and the variation is equal to this difference.

PROBLEM XXIV.

The latitude, hour of the day, and the Sun's place, being given; to find the Sun's altitude and azimuth.

Rectify the globe, and turn it until the index points to the given hour; then lay the quadrant of altitude over the fun's place in the ecliptic, and the degree of the quadrant cut by the fun's place is his altitude at that time above the horizon; and the degree of the horizon cut by the quadrant is the fun's azimuth, reckoned from the fouth.

PROBLEM XXV.

The latitude, the fun's altitude, and his azimuth being given; to find his place in the ecliptic, the day of the month, and bour of the day, though they had all been loft.

Rectify the globe for the latitude and * zenith, and fet the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude: that point of the ecliptic which cuts the quadrant there, will be the fun's place; and the day of the month anfwering thereto, will be found over the like place of the fun on the wooden horizon. Keep the quadrant of altitude in that polition, and having brought the fun's place to the brafen meridian, and the hour index to XII at noon, turn back the globe, until the fun's place cuts the quadrant of altitude again, and the index will fhew the hour.

Any two points of the ecliptic which are equidiftant from the beginning of *Cancer* or of *Capricorn*, will have the fame altitude and azimuth at the fame hour, though the months be different; and therefore it requires fome care in this problem, not to miftake both the month, and the day of the month; to avoid which obferve, that from the 20th of March to the 21ft of June, that part of the ecliptic which is be-

* By rectifying the globe for the zenith, is meant forewing the quadrant of altitude to the given latitude on the brafs meridian.

tween

tween the beginning of Aries and beginning of Cancer is to be ufed: from the 21ft of June to the 23d of September, between the beginning of Cancer and beginning of Libra: from the 23d of September to the 21ft of December, between the beginning of Libra and the beginning of Capricorn; and from the 21ft of December to the 20th of March, between the beginnining of Capricorn and beginning of Aries. And as one can never be at a lofs to know in what quarter of the year he takes the fun's altitude and azimuth, the above caution with regard to the quarters of the ecliptic, will keep him right as to the month and day thereof.

PROBLEM XXVI.

To find the length of the longest day at any given place.

If the place be on the north fide of the equator, find its latitude (by Prob. 1.) and elevate the north pole to that latitude ; then, bring the beginning of Cancer on to the brasen meridian, and fet the hour-index to XII at noon. But if the given place be on the fouth fide of the equator, elevate the fouth pole to its latitude, and bring the beginning of Capricorn by to the brass meridian, and the hour-index to XII. This done, turn the globe weftward, until the beginning of Canser or Capricorn (as the latitude is north or fouth) comes to the horizon; and the index will then point out the time of funfetting, for it will have gone over all the afternoon hours, between mid-day and fun-fet; which

which length of time being doubled, will give the whole length of the day, from fun-rifing to fun-fetting. For, in all latitudes, the fun rifes as long before mid day, as he fets after it.

PROBLEM XXVII.

To find in what latitude the longest day is of any given length less than 24 hours.

If the latitude be north, bring the beginning of Cancer to the brafen meridian, and elevate the north pole to about $66\frac{x}{2}$ degrees; but if the latitude be fouth, bring the beginning of Capricorn to the meridian, and elevate the fouth pole to about 661 degrees ; because the longest day in north latitude, is when the fun is in the first point of Cancer; and in fouth latitude, when he is in the first point of Capricorn. Then fet the hour-index to XII at noon, and turn the globe weftward, until the index points at half the number of hours given : which done, keep the globe from turning on its axis, and flide the meridian down in the notches, until the aforefaid point of the ecliptic (viz. Cancer or Capricorn) comes to the horizon; then, the elevation of the pole will be equal to the latitude required.

288

PRO-

PROBLEM XXVIII.

The latitude of any place, not exceeding $66\frac{1}{2}$ degrees being given; to find in what * climate the place is.

Find the length of the longest day at the given place by Prob. XXVI. and whatever be the number of hours whereby it exceedeth twelve, double that number, and the fum will answer to the climate in which the place is.

PROBLEM XXIX.

The latitude, and the day of the month, being given; to find the hour of the day when the fun fhines.

Set the wooden horizon truly level, and the brafen meridian due north and fouth by a mariner's compafs: then, having rectified the globe, flick a fmall fewing-needle into the fun's place in the ecliptic, perpendicular to that part of the furface of the globe: this done, turn the globe on its axis, until the needle comes to the brafen meridian, and fet the hour-index to XII

* A climate, from the equator to either of the polar circles, is a tract of the earth's furface, included between two fuch parallels of latitude, that the length of the longeft day in the one exceeds that in the other by half an hour; but from the polar circles to the poles, where the fun keeps long above the horizon without fetting, each climate differs a whole month from the one next to it. There are twentyfour climates between the equator and each of the polar circles; and fix from each polar circle to its refpective pole.

at noon; then, turn the globe on its axis, until the needle points exactly towards the fun (which it will do when it cafts no fhadow on the globe) and the index will fhew the hour of the day.

PROBLEM XXX.

A pleafant way of shewing all those places of the earth which are enlightened by the fun, and also the time of the day when the fun shines.

Take the terreftrial ball out of the wooden horizon, and also out of the brafen meridian; then fet it upon a pedestal in fun-fhine, in fuch a manner, that its north pole may point directly towards the north pole of the heaven, and the meridian of the place where you are be directly towards the fouth. Then, the fun will fhine upon all the like places of the globe, that he does on the real earth, rifing to fome when he is fetting to others; as you may perceive by that part where the enlightened half of the globe is divided from the half in the shade, by the boundary of the light and darkness : all those places, on which the fun fhines, at any time, having day; and all those, on which he does not shine, having night.

If a narrow flip of paper be put round the equator, and divided into 24 equal parts, beginning at the meridian of your place, and the hours be fet to those divisions in such a manner, that one of the VI's may be upon your meridian; the such that meridian at noon, will then shine exactly to the two XII's; and at one o'clock to the two I's, &c. So that the place,

Observations concerning it.

place, where the enlightened half of the globe is parted from the fhaded half, in this circle of hours, will fhew the time of the day.

The principles of dialing thall be explained farther on, by the terrefirial globe. At prefent we thall only add the following observations upon it; and then proceed to the use of the celeftial globe.

1. The latitude of any place is equal to the elevation of the pole above the korizon of that place, and the elevation of the equator is equal to the complement of the latitude, that is, to what the latitude wants of 90 degrees.

2. I bose places which lie on the equator, have no latitude, it being there that the latitude begins; and those places which lie on the first meridian have no longitude, it being there that the longitude begins. Consequently, that particular place of the earth where the first meridian intersects the equator, has neither longitude nor latitude.

3. At all places of the earth, except the poles, all the points of the compass may be diftinguished in the horizon: but from the north pole, every place is south; and from the south pole, every place is north. Therefore, as the fun is constantly above the horizon of each pole for half a year in its turn, be cannot be faid to depart from the meridian of either pole for half a year together. Consequently, at the north pole it may be faid to be noon every moment for half a year; and let the winds blow from what part they will, they must always blow from the fouth; and at the fouth pole, from the north.

4. Because one half of the ecliptic is above the horizon of the pole, and the fun, moon, and planets move in (or nearly in) the ecliptic; they will all U rife

Observations concerning the

rife and fet to the poles. But, becaufe the ftars never change their declinations from the equator (at leaft not fenfibly in one age) those which are once above the horizon of either pole, never set below it; and those which are once below it, never rise.

F. All places of the earth do equally enjoy the benefit of the fun, in respect of time, and are equally deprived of it.

6. All places upon the equator have their days and nights equally long, that is, 12 hours each, at all times of the year. For although the fun declines alternately, from the equator towards the north and towards the fouth, yet, as the horizon of the equator cuts all the parallels of latitude and declination in halves, the fun must always continue above the horizon for one half a diurnal revolution about the earth, and for the other half below it.

7. When the fun's declination is greater than the latitude of any place, upon either fide of the equator, the fun will come twice to the same azimuth or point of the compass in the forenoon, at that place, and twice to a like azimuth in the afternoon; that is, be will go twice back every day, whilf his declination continues to be greater than the latitude. Thus, suppose the globe restified to the latitude of Barbadoes, which is 13 degrees north; and the fun to be any where in the ecliptic, between the middle of Taurus and middle of Leo; if the quadrant of altitude be fet to about * 18 degrees north of the east in the borizon, the fun's place be marked with a chalk upon the ecliptic, and the globe be then turned westward on its axis, the faid mark will rife in the borizon a little to the north of the quadrant, and thence alcending, it will cross the quadrant towards

* From the middle of Gemini to the middle of Cancer, the quadrant may be fet 20 degrees.

the

Terrestrial Globe.

the fouth; but before it arrives at the meridian, it will crofs the quadrant again, and pafs over the meridian northward of Barbadoes. And if the quadrant be fet about 18 degrees north of the west, the sun's place will crofs it twice, as it descends from the meridian towards the horizon, in the asternoon.

8. In all places of the earth between the equator and poles, the days and nights are equally long, viz. 12 hours each, when the sun is in the equinostial: for, in all elevations of the pole, short of 90 degrees (which is the greatest) one half of the equator or equinostial will be above the horizon, and the other half below it.

9. The days and nights are never of an equal length at any place between the equator and polar circles, but when the fun enters the figns ∞ Aries and ∞ Libra. For in every other part of the ecliptic, the circle of the fun's daily motion is divided into two unequal parts by the horizon.

10. The nearer that any place is to the equator, the lefs is the difference between the length of the days and nights in that place; and the more remote, the contrary. The circles which the fun defcribes in the beaven every 24 hours, being cut more nearly equal in the former cafe, and more unequally in the latter.

11. In all places lying upon any given parallel of latitude, bowever long or fhort the day or night be at any one of these places, at any time of the year, it is then of the same length at all the rest; for in turning the globe round its axis (when restified according to the sun's declination) all these places will keep equally long above or below the borizon.

12. The fun is vertical twice a year to every place between the tropics; to those under the tropics, U 2 once

Observations concerning the

once a year, but never any where elfe. For, there can be no place between the tropics, but that there will be two points in the ecliptic, whose declination from the equator is equal to the latitude of that place; and but one point of the ecliptic which has a declination equal to the latitude of places on the tropic which that point of the ecliptic touches; and as the fun never goes without the tropics, be can never be vertical to any place that lies without them.

13. To all places in the * torrid zone, the duration of the twilight is least, because the sun's daily motion is the most perpendicular to the borizon. In the frigid \uparrow zones, greatest; because the sun's daily motion is nearly parallel to the horizon; and therefore he is the longer of getting 18 degrees below it (till which time the twilight always continues.) And in the \ddagger temperate zones it is at a medium between the two, because the obliquity of the sun's daily motion is so.

14. In all places lying exactly under the polar circles, the fun, when he is in the neareft tropic, continues 24 hours above the horizon without fetting; becaufe no part of that tropic is below their horizon. And when the fun is in the fartheft tropic, he is for the fame length of time without rifing; becaufe no part of that tropic is above their horizon. But, at all other times of the year, he rifes and fets there, as in other places; becaufe all the circles that can be drawn parallel to the equator, between the tropics, are more or lefs cut by the horizon, as they are farther from, or nearer to, that tropic which is all above the horizon : and

- * Between the tropics.
- + Between the polar circles and poles.
- I Between the tropics and polar circles.

when

Terrestrial Globe.

when the fun is not in either of the tropics, his diurnal course must be in one or other of these circles.

15. To all places in the northern hemisphere, from the equator to the polar circle, the longest day and shortest night is when the sun is in the northern tropic; and the shortest day and longest night is when the sun is in the southern tropic; because no circle of the sun's daily motion is so much above the borizon, and so little below it, as the northern tropic; and none so little above it, and so much below it, as the southern. In the southern hemisphere, the contrary.

16. In all places between the polar circles and poles, the fun appears for fome number of days (or rather diurnal revolutions) without fetting; and at the opposite time of the year without rising; because some part of the ecliptic never sets in the former case, and as much of the opposite part never rises in the latter. And the nearer unito, or the more remote from the pole, these places are, the longer or shorter is the sun's continuing presence or absence.

17. If a ship sets out from any port, and sails round the earth eastward to the fame port again, let her take what time she will to do it in, the people in that ship, in reckoning their time, will gain one complete day at their return, or count one day more than those who reside at the same port; because, by going contrary to the sun's diurnal motion, and being forwarder every evening than they were in the morning, their borizon will get fo much the sooner above the setting fun, than if they had kept for a whole day at any particular place. And thus, by cutting off a part proportionable to their own motion, from the length of every day, they will gain a complete day of that fort at their return; without gaining one moment of absolute time more U 3 then

than is elapsed during their course, to the people at the port. If they fail westward, they will reckon one day lefs than the people do who refide at the laid port, because by gradually following the apparent diurnal motion of the fun, they will keep bim cach particular day so much longer above their horizon, as anfwers to that day's courfe; and by that means, they cut off a whole day in reckoning, at their return, without lofing one moment of absolute time.

Hence, if two ships should set out at the same time from any port, and fail round the glube, one eastward and the other westward, fo as to meet at the same port on any day whatever; they will differ two days in reckoning their time, at their return. If they fail twice round the earth, they will differ four days; if thrice, then fix, Sc.

LECT. IX.

The use of the celestial globe, and armillary fobere.

To rectify it.

The celes. A VING done for the prefent with the tial globe. I terrestrial globe, we shall proceed to the use of the celestial; first premising, that as the equator, ecliptic, tropics, polar circles, horizon, and brafen meridian, are exactly alike on both globes, all the former problems concerning the fun are folved the fame way by both globes. The method alfo of rectifying the celeftial globe is the fame as rectifying the terrestrial, viz. Elevate the pole according to the latitude of your place, then forew the quadrant of altitude to the zenith, on the brafs meridian ; bring the fun's place in the ecliptic to the graduated edge of the brafs meridian, on the fide

fide which is above the fouth point of the wooden horizon, and fet the hour-index to the uppermoft XII, which ftands for noon.

N. B. The fun's place for any day of the year flands directly over that day on the horizon of the celeftial globe, as it does on that of the terrestrial.

The latitude and longitude of the ftars, and of Latitude all other celeftial phenomena, are reckoned in a and longivery different manner from the latitude and fude of the longitude of places on the earth : for all terreftrial latitudes are reckoned from the equator; and longitudes from the meridian of fome remarkable place, as of London by the British, and of Paris by the French; though most of the French maps begin their longitude at the meridian of the ifland Ferro .---- But the aftronomers of all nations agree in reckoning the latitudes of the moon, ftars, planets, and comets, from the ecliptic; and their longitudes from the * equinoElial colure, in that femicircle of it which cuts the ecliptic at the beginning of Aries or ; and thence eastward, quite round, to the fame femicircle again. Confequentty those ftars which lie between the equinoctial and the northern half of the ecliptic, have north declination and fouth latitude; those which lie between the equinoctial and the fouthern half of the ecliptic, have fouth declination and north latitude; and

* The great circle that passes through the equinoctial points at the beginning of ∞ and \simeq , and through the poles of the woorld (which are two opposite points, each 90 degrees from the equinoctial) is called the equinostial colure : and the Colures. great circle that passes through the beginning of 25 and 19, and also through the poles of the ecliptic, and poles of the world, is called the folfitial colure.

297

04

all

all those which lie between the tropics and poles, have their declinations and latitudes of the fame denomination.

There are fix great circles on the celeftial globe, which cut the ecliptic perpendicularly, and meet in two opposite points in the polar circles; which points are each ninety degrees from the ecliptic, and are called its poles. These polar points divide those circles into 12 femicircles; which cut the ecliptic at the beginnings of the 12 figns. They refemble fo many meridians on the terreftrial globe; and as all places which lie under any particular meridian femicircle on that globe; have the fame longitude, fo all those points of the heaven, through which any one of the above femicircles are drawn, have the fame longitude .- And as the greatest latitudes on the earth are at the north and fouth poles of the earth, fo the greatest latitudes in the heaven, are at the north and fouth poles of the ecliptic.

Confiellations.

In order to diffinguish the flars, with regard to their fituations and positions in the heaven, the ancients divided the whole visible firmament of flars into particular fystems, which they called *constellations*; and digested them into the forms of such animals as are delineated upon the celestial globe. And those flars which lie between the figures of those imaginary animals, and could not be brought within the compass of any of them, were called *unformed stars*.

Becaufe the moon and all the planets were obferved to move in circles or orbits which crofs the ecliptic (or line of the fun's path) at fmall angles, and to be on the north fide of the ecliptic for one half of their courfe round the heaven of ftars, and on the fouth fide of it for the other

other half, but never to go quite 8 degrees from it on either fide, the ancients diffinguifhed that fpace by two leffer circles, parallel to the ecliptic (one on each fide) at 8 degrees diffance from it. And the fpace included between the circles, they called the zodiac, becaufe most of the 12 conftellations placed therein refemble fome living creature.—These conftellations are, I. Aries \mathfrak{P} , the ram; 2. Taurus 8, the bull; 3. Gemini II, the twins; 4. Cancer \mathfrak{B} , the crab; 5. Leo \mathfrak{A} , the lion; 6. Virgo \mathfrak{M} , the virgin: 7. Libra \mathfrak{L} , the balance; 8 Scorpio \mathfrak{M} , the forpion; 9. Sagittarius \mathfrak{L} , the archer; 10. Capricornus \mathfrak{P} , the goat; 11. Aquarius \mathfrak{M} , the water bearer; and 12. Pifces \mathfrak{K} , the fifthes.

It is to be obferved, that in the infancy of Remark. aftronomy, thefe twelve confiellations flood at or near the places of the ecliptic, where the above characteriftics are marked upon the globe ; but now, each confiellation has got a whole fign forwarder, on account of the receffion of the equinoftial points from their former places. So that the confiellation of Aries, is now in the former place of Taurus; that of Taurus, in the former place of Gemini; and fo on.

The ftars appear of different magnitudes to the eye; probably becaufe they are at different diffances from us. Those which appear brighteft and largeft, are called *ftars of the first magnitude*; the next to them in fize and luftre, are called *ftars of the fecond magnitude*; and fo on to the *fixtb*, which are the fmalleft that can be differend by the bare eye.

Some of the most remarkable stars have names given them, as Castor and Polluw in the heads of the Twins, Sirius in the mouth of the Great Dog, Procyon in the side of the Little Dog, Rigel in

in the left foot of Orion, Artiurus near the right thigh of Bootes, &cc.

These things being premised, which I think are all that the young *Tyro* need be acquainted with, before he begins to work any problem by this globe, we shall now proceed to the most useful of those problems; omitting several which are of little or no confequence.

PROBLEM I.

To find the * right ascension and + declination of the sun, or any fixed star.

Bring the fun's place in the ecliptic to the brafen meridian, then that degree in the equinoctial which is cut by the meridian, is the fun's *right afcenfion*; and that degree of the meridian which is over the fun's place, is his *declination*. Bring any fixed ftar to the meridian, and its *right afcenfion* will be cut by the meridian in the equinoctial; and the degree of the meridian that ftands over it, is its *declination*.

So that right ascension and declination, on the celeftial globe, are found in the same manner as longitude and latitude on the terrestrial.

* The degree of the equinoctial, reckoned from the beginning of Aries, that comes to the meridian with the fun or flar, is its right a fcen fion.

† The diffance of the fun or flar in degrees from the equinoctial, towards either of the poles, north or fouth, is its declination, which is north or fouth accordingly.

the support for

PROS

PROBLEM II.

To find the latitude and longitude of any flar.

If the given ftar be on the north fide of the ecliptic, place the goth degree of the quadrant of altitude on the north pole of the ecliptic, where the twelve femicircles meet; which divide the ecliptic into the 12 figns : but if the ftar be on the fouth fide of the ecliptic, place the goth degree of the quadrant on the fouth pole of the ecliptic : keeping the 90th degree of the quadrant on the proper pole, turn the quadrant about, until its graduated edge cuts the ftar : then, the number of degrees in the quadrant, between the ecliptic and the ftar, is its latitude; and the degree of the ecliptic cut by the quadrant is the ftar's longitude, reckoned according to the fign in which the quadrant then is.

PROBLEM III.

To reprefent the face of the ftarry firmament, as feen from any given place of the earth, at any bour of the night.

Rectify the celeftial globe for the given latitude, the zenith, and fun's place, in every refpect, as taught by the 17th problem, for the terreftrial; and turn it about, until the index points to the given hour : then, the upper hemifphere of the globe will reprefent the vifible half of the heaven for that time : all the ftars upon

upon the globe being then in fuch fituations, as exactly correspond to those in the heaven. And if the globe be placed duly north and fouth, by means of a finall fea-compais, every ftar on the globe will point toward the like ftar in the heaven: by which means, the conftellations and remarkable ftars may be eafily known. All those ftars which are in the eastern fide of the horizon, are then rifing in the eaftern fide of the heaven; all in the weftern, are fetting in the weftern fide; and all those under the upper part of the brafen meridian, between the fouth point of the horizon and the north pole, are at their greatest altitude, if the latitude of the place be north : but if the latitude be fouth, those ftars which lie under the upper part of the meridian, between the north point of the horizon and the fouth pole, are at their greatest altitude.

PROBLEM IV.

The latitude of the place, and day of the month, being given; to find the time when any known ftar will rife, or be on the meridian, or (et.

Having rectified the globe, turn it about until the given ftar comes to the eaftern fide of the horizon, and the index will fhew the time of the ftar's rifing; then turn the globe weftward, and when the ftar comes to the brafen meridian, the index will fhew the time of the ftar's coming to the meridian of your place; laftly, turn on, until the ftar comes to the weftern fide of the horizon, and the index will fhew the time of the ftar's fetting.

N. B.

302.

N. B. In northern latitudes, those stars which are lefs distant from the north pole, than the quantity of its elevation above the north point of the horizon, never set; and those which are lefs distant from the south pole, than the number of degrees by which it is depressed below the horizon, never rife: and vice versa in southern latitudes.

PROBLEM V.

To find at what time of the year a given star will be upon the meridian, at a given hour of the night.

Bring the given flar to the upper femicircle of the brafs meridian, and fet the index to the given hour; then turn the globe, until the index points to XII at noon, and the upper femicircle of the meridian will then cut the fun's place, anfwering to the day of the year fought; which day may be eafily found against the like place of the fun among the figns on the wooden horizon.

PROBLEM VI.

The latitude, day of the month, and * azimuth of any known star being given; to find the hour of the night.

Having rectified the globe for the latitude, zenith, and fun's place; lay the quadrant of

* The number of degrees that the fun, moon, or any flar, is from the meridian, either to the eaft or weft, is called its azimuth.

altitude

altitude to the given degree of azimuth in the horizon: then turn the globe on its axis, until the ftar comes to the graduated edge of the quadrant; and when it does, the index will point out the hour of the night.

PROBLEM VII.

The latitude of the place, the day of the month, and altitude * of any known star, being given; to find the hour of the night.

Rectify the globe as in the former problem, guefs at the hour of the night, and turn the globe until the index points at the fuppofed hour; then lay the graduated edge of the quadrant of altitude over the known ftar, and if the degree of the ftar's height in the quadrant upon the globe, anfwers exactly to the degree of the ftar's observed altitude in the heaven, you have gueffed exactly : but if the ftar on the globe is higher or lower than it was observed to be in the heaven, turn the globe backwards or forwards, keeping the edge of the quadrant upon the ftar, until its center comes to the observed altitude in the quadrant; and then, the index will fhew the true time of the night.

* The number of degrees that the flar is above the horizon, as observed by means of a common quadrant, is called its *altitude*.

PRO.

PROBLEM VIII.

An easy method for finding the bour of the night by any two known stars, without knowing either their altitude or azimuth; and then, of finding both their altitude and azimuth, and thereby the true meridian.

Tie one end of a thread to a common mufket bullet; and, having rectified the globe as above, hold the other end of the thread in your hand, and carry it flowly round betwixt your eye and the ftarry heaven, until you find it cuts any two known ftars at once. Then, gueffing at the hour of the night, turn the globe until the index points to the time in the hour-circle; which done, lay the graduated edge of the quadrant over any one of these two stars on the globe, which the thread cut in the heaven. If the faid edge of the quadrant cuts the other ftar alfo, you have gueffed the time exactly; but if it does not, turn the globe flowly backwards or forwards, until the quadrant (kept upon either ftar) cuts them both through their centers : and then, the index will point out the exact time of the night; the degree of the horizon, cut by the quadrant, will be the true azimuth of both these ftars from the fouth; and the ftars themfelves will cut their true altitudes in the quadrant. At which moment, if a common azimuth compass be fo fet upon a floor or level pavement, that these flars in the heaven may have the fame bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and fouth points of that compass will
will be directly in the plane of the meridian: and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the southmost end of the line, the shadow of the wire will fall upon that line, when the fun is on the meridian, and shines upon the pavement.

PROBLEM IX.

To find the place of the moon, or of any planet; and thereby to Shew the time of its rising, southing, and setting.

Seek in *Parker*'s or *White*'s Ephemeris the * geocentric place of the moon or planet in the ecliptic, for the given day of the month, and, according to its longitude and latitude, as fhewn by the Ephemeris, mark the fame with a chalk upon the globe. Then, having rectified the globe, turn it round its axis weftward; and as the faid mark comes to the eaftern fide of the horizon, to the brafen meridian, and to the weftern fide of the horizon, the index will fhew at what time the planet rifes, comes to the meridian, and fets, in the fame manner as it would do for a fixed ftar.

PROBLEM X.

To explain the phenomena of the harvest moon.

In order to do this, we must premise the following things. 1. That as the fun goes only

* The place of the moon or planet, as feen from the earth, is called its geocentric place.

3

once

once a year round the ecliptic, he can be but once a year in any particular point of it: and that his motion is almost a degree every 24 hours, at a mean rate. 2. That as the moon goes round the ecliptic once in 27 days and 8 hours, the advances 135 degrees in it, every day at a mean rate. 3. That as the fun goes through part of the ecliptic in the time the moon goes round it, the moon cannot at any time be either in conjunction with the fun, or oppofite to him, in that part of the ecliptic where the was fo the last time before : but must travel as much forwarder, as the fun has advanced in the faid time : which being 29' days, makes almost a whole fign. Therefore, 4. The moon can be but once a year opposite to the fun, in any particular part of the ecliptic. 5. That the moon is never full but when the is opposite to the fun, becaufe at no other time can we fee all that half of her, which the fun enlightens. 6. That when any point of the ecliptic rifes, the oppofite point fets. Therefore, when the moon is oppofite to the fun, fhe must rife at * fun fet. 7. That the different figns of the ecliptic rife at very different angles or degrees of obliquity with the horizon, especially in confiderable latitudes; and that the fmaller this angle is, the greater is the portion of the ecliptic that rifes in any fmall part of time ; and vice versa. 8. That, in northern latitudes, no part of the ecliptic rifes at fo fmall an angle with the horizon, as Pifces and Aries do; therefore, a greater portion of the ecliptic rifes in

• This is not always firifuly true, becaufe the moon does not keep in the ecliptic, but croffes it twice every month. However, the difference need not be regarded in a general explanation of the caufe of the harveft moon.

X

one

one hour, about these figns, than about any of the reft. 9. That the moon can never be full in *Pisces* and *Aries* but in our autumnal months, for at no other time of the year is the fun in the opposite figns *Virgo* and *Libra*.

These things premised, take $13\frac{1}{6}$ degrees of the ecliptic in your compasses, and beginning at *Pisces*, carry that extent all round the ecliptic, marking the places with a chalk, where the points of the compasses fucceffively fall. So you will have the moon's daily motion marked out for one complete revolution in the ecliptic (according to § 2 of the last paragraph.)

Rectify the globe for any confiderable northern latitude, (as fuppofe that of London) and then, turning the globe round its axis, observe how much of the hour circle the index has gone over, at the rifing of each particular mark on the ecliptic; and you will find that feven of the marks (which take in as much of the ecliptic as the moon goes through in a week) will all rife fucceffively about Pifces and Aries in the time that the index goes over two hours. Therefore, whilft the moon is in Pifces and Aries, the will not differ in general above two hours in her rifing for a whole week. But if you take notice of the marks on the opposite figns, Virgo and Libra, you will find that leven of them take nine hours to rife; which fhews, that when the moon is in these two figns, she differs nine hours in her riling within the compass of a week. And fo much later as every mark is of rifing than the one that role next before it, fo much later will the moon be of riling on any day than fhe was on the day before, in the corresponding part of the heaven. The marks about Cancer and Capricorn rile

rife at a mean difference of time between those about Aries and Libra.

Now, although the moon is in *Pifees* and *Aries* every month, and therefore mult rife in those figns within the space of two hours later for a whole week, or only about 17 minutes later every day then she did on the former; yet she is never full in these signs, but in our autumnal months, *August* and *September*, when the fun is in *Virgo* and *Libra*. Therefore, no full moon in the year will continue to rife so near the time of fun set for a week or so, as these two full moons do, which fall in the time of harvest.

In the winter months, the moon is in *Pifess* and *Aries* about her first quarter; and as thefe figns rife about noon in winter, the moon's rifing in them paffes unobferved. In the fpring months, the moon changes in thefe figns, and confequently rifes at the fame time with the fun; fo that it is impoffible to fee her at that time. In the fummer months she is in these figns about her third quarter, and rifes not until mid-night, when her rifing is but very little taken notice of; especially as she is on the decrease. But in the harvest months she is at the full, when in these shear the fun fets (or foon after) and shines all the night.

In fouthern latitudes, Virgo and Libra rife at as fmall angles with the horizon, as Pifces and Aries do in the northern; and as our fpring is at the time of their harveft, it is plain their harveft full moons muft be in Virgo and Libra; and will therefore rife with as little difference of time, as ours do in Pifces and Aries.

X 2

For

For a fuller account of this matter, I mult refer the reader to my Aftronomy, in which it is defcribed at large.

PROBLEM XI.

To explain the equation of time, or difference of time between well regulated clocks and true fun-dials.

The earth's motion on its axis being perfectly equable, and thereby caufing an apparent equable motion of the ftarry heaven round the fame axis, produced to the poles of the heaven; it is plain that equal portions of the celeftia equator pafs over the meridian in equal parts of time, becaufe the axis of the world is perpendicular to the plane of the equator. And therefore, if the fun kept his annual courfe in the celeftial equator, he would always revolve from the meridian to the meridian again in 24 hours exactly, as fhewn by a well-regulated clock.

But as the fun moves in the ecliptic, which is oblique both to the plane of the equator and axis of the world, he cannot always revolve from the meridian to the meridian again in 24 equal hours; but fometimes a little fooner, and at other times a little latter, becaufe equal portions of the ecliptic pafs over the meridian in unequal parts of time on account of its obliquity. And this difference is the fame in all latitudes.

To fhew this by a globe, make chalk-marks all round the equator and ecliptic, at equal diffances from one another (fuppole 10 degrees) beginning at Aries or at Libra, where these two circles interfect each other. Then turn the globe

The UJe of the Terrestrial Globe.

globe round its axis, and you will fee that all the marks in the first quadrant of the ecliptic, or from the beginning of Aries to the beginning of Cancer, come fooner to the brafen meridian than their corresponding marks do on the equator: those in the fecond quadrant, or from the beginning of Cancer to the beginning of Libra, come later: those in the third quadrant, from Libra to Capricorn, fooner; and those in the fourth, from Capricorn to Aries, later. But those at the beginning of each quadrant come to the meridian at the fame time with their corresponding marks on the equator.

Therefore, whilft the fun is in the firft and third quadrants of the ecliptic, he comes fooner to the meridian every day than he would do if he kept in the equator; and confequently he is fafter than a well regulated clock, which always keeps equable or equatorial time: and whilft he is in the fecond and fourth quadrants, he comes latter to the meridian every day than he would do if he kept in the equator; and is therefore flower than the clock. But at the beginning of each quadrant, the fun and clock are equal.

And thus, if the fun moved equably in the ecliptic, he would be equal with the clock on four days of the year, which would have equal intervals of time between them. But as he moves fafter at fome times than at others (being eight days longer in the northern half of the ecliptic than in the fouthern) this will caufe a fecond inequality; which combined with the former, arifing from the obliquity of the ecliptic to the equator, makes up that difference, which is fhewn by the common equation tables to be between good clocks and true fun-dials.

The

The description and use of the armillary Sphere.

Plate XX. Fig. 1. a

Whoever has feen a common armillary fpbere, and understands how to use it, must be fensible that the machine here referred to, is of a very different, and much more advantageous conftruction. And those who have seen the curious glass fphere invented by Dr. Long, or the figure of it in his Aftronomy, muft know that the furniture of the terreftrial globe in this machine, the form of the pedeftal, and the manner of turning either the earthly globe or the circles which furround it, are all copied from the Doctor's glafs fphere; and that the only difference is, a parcel of rings inftead of a glafs celeftial globe; and all the additions are a moon within the fphere, and a femicircle upon the pedeftal.

The armiliary lobere.

The exterior parts of this machine are a compages of brafs rings, which reprefent the principal circles of the heaven, viz. 1. The equinoctial A A, which is divided into 360 degrees, (beginning at its interfection with the ecliptic in Aries) for shewing the fun's right ascension in degrees; and also into 24 hours, for shewing his right ascention in time. 2. The ecliptic B B, which is divided into 12 figns, and each fign into 30 degrees, and alfo into the months and days of the year; in fuch a manner, that the degree or point of the ecliptic in which the fun is, on any given day, ftands over that day in the circle of months. 3. The tropic of Cancer CC, touching the ecliptic at the beginning of Cancer in e, and the tropic of Capricorn D D, touching the ecliptic at the beginning of Capricorn in f_i each $23\frac{1}{2}$ degrees trom

from the equinoctial circle. 4. The arctic circle E, and the antarctic circle F, each $23\frac{1}{2}$ degrees from its respective pole at N and S. 5. The equinoctial colure GG, paffing through the north and fouth poles of the heaven at N and S. and through the equinoctial points Aries, and Libra in the ecliptic. 6. The folfitial colure HH, paffing through the poles of the heaven, and through the folftitial points Cancer and Capricorn, in the ecliptic. Each quarter of the former of thefe colures is divided into go degrees, from the equinoctial to the poles of the world, for fhewing the declination of the fun, moon, and ftars; and each quarter of the latter, from the ecliptic at e and f, to its poles b and d, for shewing the latitude of the ftars.

In the north pole of the ecliptic is a nut b, to which is fixed one end of a quadrantal wire, and to the other end a fmall fun \mathcal{X} , which is carried round the ecliptic B B, by turning the nut: and in the fouth-pole of the ecliptic is a pin at d, on which is another quadrantal wire, with a fmall moon Z upon it, which may be moved round by hand: but there is a particular contrivance for caufing the moon to move in an orbit which croffes the ecliptic at an angle of $5\frac{x}{3}$ degrees, in two opposite points called the moon's nodes; and also for fhifting these points backward in the ecliptic, as the moon's nodes fhift in the heaven.

Within thefe circular rings is a fmall terreftrial globe I, fixt on an axis K K, which extends from the north and fouth poles of the globe at nand s, to those of the celeftial fphere at N and S. On this axis is fixt the flat celeftial meridian L L, which may be fet directly over the meridian of any place on the globe, and then turned round with the globe, fo as to keep over the fame X 4 meridian

meridian upon it. This flat meridian is graduated the fame way as the brafs meridian of a common globe, and its use is much the fame. To this globe is fitted the moveable horizon MM, fo as to turn upon two ftrong wires proceeding from its east and west points to the globe, and entering the globe at oppofite points of its equator, which is a moveable brafs ring let into the globe in a groove all around its equator. The globe may be turned by hand within this ring, fo as to place any given meridian upon it, directly under the celeftial meridian LL. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass, for fhewing the amplitude of the fun and moon, both in degrees and points. The celeftial meridian LL paffes through two notches in the north and fouth points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the fouth pole of the fphere is a circle of 24 hours, fixt to the rings, and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is fupported on a pedeftal N, and may be elevated or deprefied upon the joint O, to any number of degrees from 0 to 90, by means of the arc P, which is fixed in the frong brafs arm \mathcal{Q} , and flides in the upright piece R, in which is a forew at r, to fix it at any proper elevation.

In the box T are two wheels (as in Dr. Long's fphere) and two pinions, whofe axes come out at V and U; either of which may be turned by the fmall winch W. When the winch is put upon the axis V, and turned backward, the terreftrial

reftrial globe, with its horizon and celeftial meridian, keep at reft; and the whole fphere of circles turns round from eaft, by fouth, to weft, carrying the fun Y, and moon Z, round the fame way, and caufing them to rife above and fet below the horizon. But when the winch is put upon the axis U, and turned forward, the fphere with the fun and moon keep at reft; and the earth, with its horizon and meridian, turn round from weft, by fouth, to east; and bring the fame points of the horizon to the fun and moon, to which these bodies came when the earth kept at reft, and they were carried round it; fhewing that they rife and fet in the fame points of the horizon, and at the fame time in the hour-circle. whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the fphere be turned, the hour-circle goes round below the index.

And fo, by this conftruction, the machine is equally fitted to fhew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the fphere for ufe, firft flacken the forew r in the upright ftem R, and taking hold of the arm \mathcal{Q} , move it up or down until the given degree of latitude for any place be at the fide of the ftem R; and then the axis of the fphere will be properly elevated, fo as to ftand parallel to the axis of the world, if the machine be fet north and fouth by a fmall compafs: this done, count the latitude from the north-pole, upon the celeftial meridian L L, down towards the north notch of the horizon, and fet the horizon to that latitude; then, turn the nut δ until the fun Υ comes to the given day of the year in the the ecliptic, and the fun will be at its proper place for that day : find the place of the moon's afcending node, and alfo the place of the moon. by an Ephemeris, and fet them right accordingly : laftly, turn the winch W, until either the fun comes to the meridian L L, or until the meridian comes to the fun (according as you want the fphere or earth to move) and fet the hourindex to the XII, marked noon, and the whole machine will be rectified ---- Then turn the winch, and obferve when the fun or moon rife and fet in the horizon, and the hour-index will fhew the times thereof for the given day.

As those who understand the use of the globes will be at no lofs to work many other problems by this fphere, it is needlefs to enlarge any farther upon it.

LECT.X.

The principles and art of dialing.

Preliminaries.

Dial is a plane, upon which lines are defcribed in fuch a manner, that the fhadow of a wire, or of the upper edge of a plate ftile, erected perpendicularly on the plane of the dial, may fhew the true time of the day.

The edge of the plate by which the time of the day is found, is called the ftile of the dial, which must be parallel to the earth's axis; and the line on which the faid plate is erected, is called the fubftile.

The angle included between the fubstile and ftile, is called the elevation, or height of the ftile.

Those dials whose planes are parallel to the plane of the horizon, are called horizontal dials; and

and those dials whose planes are perpendicular to the plane of the horizon, are called vertical, or erect dials.

Those erect dials, whose planes directly front the north or fouth, are called direct north or fouth dials; and all other creft dials are called decliners, because their planes are turned away from the north or fouth.

Those dials whose planes are neither parallel nor perpendicular to the plane of the horizon, are called inclining, or reclining dials, according as their planes make acute or obtuse angles with the horizon; and if their planes are also turned aside from facing the south or north, they are called declining-inclining, or decliningreclining dials.

The interfection of the plane of the dial, with that of the meridian, paffing through the flile, is called the meridian of the dial, or the hourline of XII.

Those meridians, whose planes pass through the ftile, and make angles of 15, 30, 45, 60, 75, and 90 degrees with the meridian of the place (which marks the hour-line of XII) are called hour-circles; and their interfections with the plane of the dial, are called hour-lines.

In all declining dials, the fubfile makes an angle with the hour-line of XII; and this angle is called the diffance of the fubfile from the meridian.

The declining plane's difference of longitude, is the angle formed at the interfection of the ftile and plane of the dial, by two meridians; one of which paffes through the hour-line of XII, and the other through the fubfile.

This much being premised concerning dials in general, we shall now proceed to explain the different methods of their construction. If the whole earth a P c p were transparent,

Fig. 2.

The univerfal principle on which dialing depends.

Plate XX. and hollow, like a fphere of glafs, and had its equator divided into 24 equal parts by fo many meridian femicircles, a, b, c, d, e, f, g, &c. one of which is the geographical meridian of any given place, as London (which is supposed to be at the point a;) and if the hours of XII were marked at the equator, both upon that meridian and the opposite one, and all the reft of the hours in order on the reft of the meridians, those meridians would be the hour-circles of London : then, if the iphere had an opake axis, as $P \to p$, terminating in the poles P and p, the fhadow of the axis would fall upon every particular meridian and hour, when the fun came to the plane of the oppofite meridian, and would confequently fhew the time at London. and at all other places on the meridian of London.

Horizontal dial.

If this fphere was cut through the middle by a folid plane ABCD, in the rational horizon of London, one half of the axis EP would be above the plane, and the other half below it; and if ftraight lines were drawn from the center of the plane, to those points where its circumference is cut by the hour-circles of the fphere, those lines would be the hour-lines of a horizontal dial for London : for the fhadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the fphere.

Fig. 3.

If the plane which cuts the fphere be upright, as AFCG, touching the given place (London) at F, and directly facing the meridian of London, don, it will then become the plane of an erect direct fouth dial: and if right lines be drawn *Vertical* from its center E, to those points of its circum-dial. ference where the hour-circles of the fphere cut it, these will be the hour lines of a vertical or direct fouth dial for London, to which the hours are to be fet as in the figure (contrary to those on a horizontal dial) and the lower half E p of the axis will caft a shadow on the hour of the day in this dial, at the fame time that it would fall upon the like hour-circle of the sphere, if the dial-plane was not in the way.

If the plane (ftill facing the meridian) be Inclining made to incline, or recline, by any given number and reof degrees, the hour circles of the fphere will clining ftill cut the edge of the plane in those points to dials. which the hour-lines must be drawn straight from the center; and the axis of the fphere will caft a shadow on these lines at the respective hours. The like will ftill hold, if the plane be Declining made to decline by any given number of degrees dials. from the meridian, towards the east or weft: provided the declination be lefs than 90 degrees, or the reclination be lefs than the co-latitude of the place: and the axis of the fphere will be a gnomon, or ftile, for the dial. But it cannot be a gnomon, when the declination is quite go degrees, nor when the reclination is equal to the co-latitude; becaufe in thefe two cafes, the axis has no elevation above the plane of the dial.

And thus it appears, that the plane of every dial reprefents the plane of fome great circle upon the earth; and the gnomon the earth's axis, whether it be a fmall wire, as in the above figures, or the edge of a thin plate, as in the common horizontal dials.

The

The whole earth, as to its bulk, is but a point, if compared to its diffance from the fun : and therefore, if a small sphere of glass be placed upon any part of the earth's furface, fo that its axis be parallel to the axis of the earth, and the fohere have fuch lines upon it, and fuch planes within it, as above deferibed; it will fnew the hours of the day as truly as if it were placed at the earth's center, and the shell of the earth were as transparent as glass.

Fig. 2, 3. But because it is impossible to have a hollow fphere of glafs perfectly true, blown round a folid plane; or if it was, we could not get at the plane within the glass to fet it in any given polition; we make use of a wire-fphere to explain the principles of dialing, by joining 24 femicircles together at the poles, and putting a thin flat plate of brafs within it.

Dialing by the common terrestial plobe.

A common globe, of 12 inches diameter, has generally 24 meridian femicircles drawn upon it. If fuch a globe be elevated to the latitude of any given place, and turned about until any one of these meridians cuts the horizon in the north point, where the hour of XII is supposed to be marked, the reft of the meridians will cut the horizon at the respective diffances of all the other hours from XII. Then, if these points of diftance be marked on the horizon, and the globe be taken out of the horizon, and a flat board or plate be put into its place, even with the furface of the horizon; and if ftraight lines be drawn from the center of the board, to those points of diftance on the horizon which were cut by the 24 meridian femicircles, thefe lines will be the hour-lines of a horizontal dial for that latitude, the edge of whole gnomon must be in the very fame fituation that the axis of the globe

globe was, before it was taken out of the horizon: that is, the gnomon muft make an angle with the plane of the dial, equal to the latitude of the place for which the dial is made.

If the pole of the globe be elevated to the * co-latitude of the given place, and any meridian be brought to the north point of the horizon, the reft of the meridians will cut the horizon in the refpective diffances of all the hours from XII, for a direct fouth dial, whole gnomon muft make an angle with the plane of the dial, equal to the co-latitude of the place; and the hours muft be fet the contrary way on this dial, to what they are on the horizontal.

But if your globe have more than 24 meridian femicircles upon it, you must take the following method for making *borizontal* and *fouth dials by it*,

Elevate the pole to the latitude of your place, To conand turn the globe until any particular meridian firuct a (fuppofe the first) comes to the north point of dist dial. the horizon and the opposite meridian will cut the horizon in the fouth. Then, fet the hourindex to the uppermoft XII on its circle; which done, turn the globe weftward until 15 degrees of the equator pass under the brasen meridian, and then the hour-index will be at I, (for the fun moves 15 degrees every hour) and the first meridian will cut the horizon in the number of degrees from the north point, that I is diftant from Turn on, until other 15 degrees of the XII. equator pals under the brafen meridian, and the hour-index will then be at II, and the first me-

* If the latitude be subtracted from 90 degrees, the remainder is called the co-latitude, or complement of the latitude.

ridian

ridian will cut the horizon in the number of degrees that II is diftant from XII: and fo, by making 15 degrees of the equator pals under the brasen meridian for every hour, the first meridian of the globe will cut the horizon in the diftances of all the hours from XII to VI, which is just go degrees; and then you need go no farther, for the diftances of XI, X, IX, VIII, VII, and VI, in the forenoon, are the fame from XII, as the diffances of I, II, III, IV, V, and VI, in the afternoon : and these hour-lines continued through the center, will give the opposite hour-lines on the other half of the dial: but no more of these lines need be drawn, than what answer to the fun's continuance above the horizon of your place on the longeft day, which may be eafily found by the 26th problem of the foregoing lecture.

Thus, to make a horizontal dial for the latitude of London, which is $51\frac{1}{2}$ degrees north, elevate the north pole of the globe $51\frac{1}{2}$ degrees above the north point of the horizon, and then turn the globe, until the first meridian (which is that of London on the English terrestrial globe) cuts the north point of the horizon, and fet the hour-index to XII at noon.

Then, turning the globe weftward until the index points fucceffively to I, II, III, IV, V, and VI, in the afternoon; or until 15, 30, 45, 60, 75, and 90 degrees of the equator pass under the brafen meridian, you will find that the first meridian of the globe cuts the horizon in the following numbers of degrees from the north towards the east, viz. $11\frac{2}{5}$ $24\frac{1}{5}$, $38\frac{1}{52}$ $53\frac{1}{52}$, $71\frac{1}{55}$, and 90; which are the respective diffances of the above hours from XII upon the plane of the horizon.

To

.

To transfer thefe, and the reft of the hours, PlateXXI. to a horizontal plane, draw the parallel right Fig. 1. lines a c and b d upon that plane, as far from each other as is equal to the intended thicknefs of the gnomon or flile of the dial, and the fpace included between them will be the meridian or twelve o'clock line on the dial. Crofs this meridian at right angles with the fix o'clock line g b, and fetting one foot of your compasses in the interfection a, as a center, describe the quadrant g e with any convenient radius or opening of the compaffes: then, fetting one foot in the interfection b, as a center, with the fame radius defcribe the quadrant f b, and divide each quadrant into 90 equal parts or degrees, as in the figure.

Becaufe the hour-lines are lefs diftant from each other about noon, than in any other part of the dial, it is beft to have the centers of thefe quadrants at a little diftance from the center of the dial-plane, on the fide opposite to XII, in order to enlarge the hour-diftances thereabout under the fame angles on the plane. Thus, the center of the plane is at C, but the centers of the quadrants at a and b.

Lay a ruler over the point b (and keeping it there for the center of all the afternoon hours in the quadrant f b) draw the hour-line of I, through $11\frac{2}{3}$ degrees in the quadrant; the hourline of II, through $24\frac{1}{4}$ degrees; of III, through $38\frac{1}{12}$ degrees; IIII, through $53\frac{1}{3}$, and V through $71\frac{1}{15}$: and becaufe the fun rifes about four in the morning, on the longeft days at London, continue the hour-lines of IIII and V, in the afternoon, through the center b to the opposite fide of the dial.—This done, lay the ruler to the center a, of the quadrant e g, and through the \mathbf{Y} like

like divisions or degrees of that quadrant, viz. $11\frac{5}{7}$, $24\frac{7}{4}$, $38\frac{7}{75}$, $53\frac{7}{2}$, and $71\frac{1}{73}$, draw the foremoon hour-lines of XI, X, IX, VIII, and VII; and becaufe the fun fets not before eight in the evening on the longeft days, continue the hourlines of VII, and VIII in the forenoon, through the center *a*, to VII and VIII in the afternoon; and all the hour-lines will be finished on this dial; to which the hours may be fet, as in the figure.

Laftly, through $51\frac{1}{2}$ degrees of either quadrant, and from its center, draw the right line agfor the hypothenule or axis of the gnomon agi; and from g, let fall the perpendicular gi, upon the meridian line ai, and there will be a triangle made, whole fides are ag, gi, and ia. If a plate fimilar to this triangle be made as thick as the diftance between the lines ac and bd, and fet upright between them, touching at a and b, its hypothenule ag will be parallel to the axis of the world, when the dial is truly fet; and will caft a fhadow on the hour of the day.

N. B. The trouble of dividing the two quadrants may be faved, if you have a fcale with a line of chords upon it, fuch as that on the right hand of the plate : for if you extend the compaffes from 0 to 60 degrees of the line of chords, and with that extent, as a radius, defcribe the two quadrants upon their refpective centers, the above diftances may be taken with the compaffes upon the line, and fet off upon the quadrants.

Fig. 2. To conftruct an erect fouth dial.

To make an erest direst fouth dial. Elevate the pole to the co-latitude of your place, and proceed in all respects as above taught for the horito zontal dial, from VI in the morning to VI in the afternoon, only the hours must be reverfed, as in the figure; and the hypothenuse ag, of the gnomon

gnomon agf, must make an angle with the dialplane equal to the co-latitude of the place. As the fun can fhine no longer on this dial, than from fix in the morning until fix in the evening, there is no occafion for having any more than twelve hours upon it.

To make an creft dial, declining from the fouth To contowards the east or west. Elevate the pole to the fluct an latitude of your place, and fcrew the quadrant of erect dealtitude to the zenith. Then, if your dial de- dial. clines towards the eaft (which we shall suppose it to do at prefent) count in the horizon the degrees of declination, from the eaft point towards the north, and bring the lower end of the quadrant to that degree of declination at which the reckoning ends. This done, bring any particular meridian of your globe (as fuppofe the first meridian) directly under the graduated edge of the upper part of the brafen meridian, and fet the hour-index to XII at noon. Then, keeping the quadrant of altitude at the degree of declination in the horizon, turn the globe eaftward on its axis, and obferve the degrees cut by the first meridian in the quadrant of altitude (counted from the zenith) as the hour-index comes to XI, X, IX, &cc. in the forenoon, or as 15, 30, 45, &c, degrees of the equator pass under the brafen meridian at these hours respectively; and the degrees then cut in the quadrant by the first meridian, are the respective distances of the forenoon hours from XII on the plane of the dial .- Then, for the afternoon hours, turn the quadrant of altitude round the zenith until it comes to the degree in the horizon opposite to that where it was placed before; namely, as far from the weft point of the horizon towards the fourh, as it was fet at first from the east point towards

Y 2

wards the north; and turn the globe weftward on its axis, until the first meridian comes to the brafen meridian again, and the hour-index to XII: then, continue to turn the globe weftward, and as the index points to the afternoon hours I, II, III, &c. or as 15, 30, 45, &c. degrees of the equator pass under the brasen meridian, the first meridian will cut the quadrant of altitude in the respective number of degrees from the zenith, that each of these hours is from XII on the dial .- And note, that when the first meridian goes off the quadrant at the horizon, in the forenoon, the hour-index fhews the time when the fun will come upon this dial: and when it goes off the quadrant in the afternoon, the index will point to the time when the fun goes off the dial.

Having thus found all the hour-diffances from XII, lay them down upon your dial-plate, either by dividing a femicircle into two quadrants of 90 degrees each (beginning at the hour-line of XII) or by the line of chords, as above directed.

In all declining dials, the line on which the flile or gnomon flands (commonly called the *jubfile-line*) makes an angle with the twelve o'clock line, and falls among the forenoon hourlines, if the dial declines towards the eaft; and among the afternoon hour-lines, when the dial declines towards the weft; that is, to the left hand from the twelve o'clock line in the former cafe, and to the right hand from it in the latter.

To find the diffance of the fubfile from the twelve o'clock line; if your dial declines from the fouth towards the eaft, count the degrees of that declination in the horizon from the eaft point toward the north, and bring the lower end of the quadrant of altitude to that degree of declination

declination where the reckoning ends: then, turn the globe until the firft meridian cuts the horizon in the like number of degrees, counted from the fouth point toward the eaft; and the quadrant and firft meridian will then crofs one another at right angles, and the number of degrees of the quadrant, which are intercepted between the firft meridian and the zenith, is equal to the diffance of the fubftile line from the twelve o'clock line; and the number of degrees of the firft meridian, which are intercepted between the quadrant and the north pole, is equal to the elevation of the file above the plane of the dial.

If the dial declines weltward from the fouth, count that declination from the eaft point of the horizon towards the fouth, and bring the quadrant of altitude to the degree in the horizon at which the reckoning ends; both for finding the forenoon hours, and the diftance of the fubfile from the meridian: and for the afternoon hours, bring the quadrant to the oppofite degree in the horizon, namely, as far from the welt towards the north, and then proceed in all refpects as above.

Thus, we have finished our declining dial; and in so doing, we made four dials, viz.

1. A north dial, declining eaftward by the fame number of degrees. 2. A north dial, declining the fame number weft. 3. A fouth dial, declining eaft. And, 4. a fouth dial declining weft. Only, placing the proper number of hours, and the ftile or gnomon refpectively, upon each plane. For (as above-mentioned) in the fouth weft plane, the fubftilar-line falls among the afternoon hours; and in the foutheaft, of the fame declination among the forenoon

Y 3

hours,

hours, at equal diffances from XII. And fo, all the morning hours on the weft decliner will be like the afternoon hours on the eaft decliner: the fouth-eaft decliner will produce the northweft decliner; and the fouth-weft decliner, the north-eaft decliner, by only extending the hourlines, ftile and fubfile, quite through the center: the axis of the ftile (or edge that cafts the fhadow on the hour of the day) being in all dials whatever parallel to the axis of the world, and confequently pointing towards the north pole of the heaven in north latitudes, and towards the fouth pole, in fouth latitudes. See more of this in the following letture.

An eafy method for conftructing of dials. But becaufe every one who would like to make a dial, may perhaps not be provided with a globe to affift him, and may probably not underftand the method of doing it by logarithmic calculation; we fhall fhew how to perform it by the plain dialing lines, or fcale of latitudes and hours; fuch as those on the right hand of Fig. 4. in Plate XXI, or at the top of Plate XXII, and which may be had on fcales commonly fold by the mathematical inftrument makers.

This is the eafieft of all mechanical methods, and by much the beft, when the lines are truly divided ; not only the half hours and quarters may be laid down by all of them, but every fifth minute by moft, and every fingle minute by those where the line of hours is a foot in length.

Having drawn your double meridian line ab, cd, on the plane intended for a horizontal dial, and croffed it at right angles by the fix o'clock line fe (as in Fig. 1.) take the latitude of your place with the compaffes, in the fcale of latitudes, and fet that extent from c to e, and from a to f, on the fix o'clock line : then, taking the whole fix hours

Fig. 3.

hours between the points of the compasses in the fcale of hours, with that extent fet one foot in the point e, and let the other foot fall where it will upon the meridian line cd, as at d. Do the fame from f to b, and draw the right lines ed and fb, each of which will be equal in length to the whole fcale of hours. This done, fetting one foot of the compaffes in the beginning of the scale at XII, and extending the other to each hour on the fcale, lay off these extents from d to e for the afternoon hours, and from b to f for those of the forenoon: this will divide the lines de and bfin the fame manner as the hour-fcale is divided, at 1, 2, 3, 4, 5 and 6; on which the quarters may also be laid down, if required. Then, laying a ruler on the point c, draw the first five hours in the afternoon, from that point, through the dots at the numeral figures 1, 2, 3, 4, 5, on the line de; and continue the lines of IIII and V through the center e to the other fide of the dial, for the like hours of the morning ; which done, lay the ruler on the point a, and draw the laft five hours in the forenoon through the dots 5, 4, 3, 2, 1, on the line f b; continuing the hour-lines of VII and VIII through the center a to the other fide uf the dial, for the like hours of the evening; and fet the hours to their refpective lines as in the figure. Laftly, make the gnomon the fame way as taught above for the horizontal dial, and the whole will be finished.

To make an crect fouth dial, take the co-latitude of your place from the fcale of latitudes, and then proceed in all refpects for the hourlines, as in the horizontal dial; only reverfing the hours, as in Fig. 2; and making the angle of the ftile's height equal to the co-latitude.

Y 4

I have

I have drawn out a fet of dialing lines upon the top of the 22d Plate, large enough for making a dial of nine inches diameter, or more inches if required; and have drawn them tolerably exact for common practice, to every quarter of an hour. This fcale may be cut off from the plate, and pasted on wood, or upon the infide of one of the boards of this book; and then it will be fomewhat more exact than it is on the place, for being rightly divided upon the copper-plate, and printed off on wet paper, it fhrinks as the paper dries : but when it is wetted again, it ftretches to the fame fize as when newly printed; and if pafted on while wet, it will remain of that fize afterwards.

But left the young dialist should have neither globe nor wooden fcale, and fhould tear or otherwife spoil the paper one in pasting, we shall now fhew him how he may make a dial without any of these helps. Only, if he has not a line of chords, he must divide a quadrant into 90 equal parts or degrees for taking the proper angle of the ftile's elevation, which is eafily done.

Fig. 4.

With any opening of the compaffes, as Z L. defcribe the two femicircles LFk and LQk, upon the centers Z and z, where the fix o'clock Horizon- line croffes the double meridian line, and divide tal dial. each femicircle into 12 equal parts, beginning at L (though, ftrictly fpeaking, only the quadrants from L to the fix o'clock line need be divided): then connect the divisions which are equidistant from L, by the parallel lines KM, IN, HO, GP, and FQ. Draw VZ for the hypothenule of the ftile, making the angle VZE equal to the latititude of your place; and continue the line VZ to R. Draw the line Rr parallel to the fix o'clock line, and fet off the diffance a K from Z to Y. the

the diftance b I from Z to X, c H from Z to W, dg from Z to T, and e F from Z to S. Then draw the lines Ss, Tt, Ww, Xx, and Yy, each parallel to Rr. Set off the diftance y T from a to II, and from f to I; the diftance x X from b to 10, and from g to 2; wW from c to 9, and from b to 3; t T from d to 8, and from i to 4; s S from e to 7, and from n to 5. Then laying a ruler to the center Z, draw the forenoon hour lines through the points 11, 10, 9, 8, 7; and laying it to the center z, draw the afternoon lines through the points 1, 2, 3, 4, 5; continuing the forenoon lines of VII and VIII through the center Z, to the opposite fide of the dial, for the like afternoon hours; and the afternoon lines IIII and V through the center z, to the opposite fide, for the like morning hours. Set the hours to these lines as in the figure, and then crect the file or gnomon, and the horizontal dial will be finished.

To conftruct a fouth dial, draw the line VZ, south making an angle with the meridian ZL equal dial. to the co-latitude of your place; and proceed in all refpects as in the above horizontal dial for the fame latitude, reverfing the hours as in Fig. 2. and making the elevation of the gnomon equal to the co-latitude.

Perhaps it may not be unacceptable to explain the method of conftructing the dialing lines, and fome others; which is as follows.

With any opening of the compafies, as E A, Plate according to the intended length of the feale, XXII. defcribe the circle A D C B, and crofs it at right angles by the diameters C E A and D E B. Fig. 1. Divide the quadrant A B first into 9 equal parts, Dialing and then each part into 10; fo shall the quadrant lines, how be divided into 90 equal parts or degrees. Draw contracted.

the right line AFB for the chord of this quadrant, and fetting one foot of the compaffes in the point A, extend the other to the feveral divifions of the quadrant, and transfer thefe divifions to the line AFB by the arcs 10 10, 20 20, &c. and this will be a line of chords, divided into 90 unequal parts; which, if transferred from the line back again to the quadrant, will divide it equally. It is plain by the figure, that the diftance from A to 60 in the line of chords, is juft equal to AE, the radius of the circle from which that line is made; for if the arc 60 60 be continued, of which A is the center, it goes exactly through the center E of the arc AB.

And therefore, in laying down any number of degrees on a circle, by the line of chords, you muft first open the compasses fo, as to take in just 60 degrees upon that line, as from A to 60; and then, with that extent, as a radius, defcribe a circle which will be exactly of the fame fize with that from which the line was divided : which done, fet one foot of the compasses in the beginning of the chord line, as at A, and extend the other to the number of degrees you want upon the line, which extent, applied to the circle, will include the like number of degrees upon it.

Divide the quadrant CD into 90 equal parts, and from each point of division draw right lines as *i*, *k*, *l*, &c. to the line CE; all perpendicular to that line, and parallel to DE, which will divide EC into a line of fines; and although these are feldom put among the dialing lines on a fcale, yet they affift in drawing the line of latitudes. For, if a ruler be laid upon the point D, and over each division in the line of fines, it will divide the quadrant CB into 90 unequal parts,

as Ba, ab, &c. fhewn by the right lines to a, 20 b, 30 c; &c. drawn along the edge of the ruler. If the right line BC be drawn, fubtending this quadrant, and the neareft diffances Ba, Bb, Bc, &c. be taken in the compafies from B, and fet upon this line in the fame manner as directed for the line of chords, it will make a line of latitudes BC, equal in length to the line of chords AB, and of an equal number of divisions, but very unequal as to their lengths.

Draw the right line D G A, fubtending the quadrant D A; and parallel to it, draw the right line r s, touching the quadrant D A at the numeral figure 3. Divide this quadrant into fix equal parts, as 1, 2, 3, &c. and through these points of division draw right lines from the center E to the line r s, which will divide it at the points where the fix hours are to be placed, as in the figure. If every fixth part of the quadrant be fubdivided into four equal parts, right lines drawn from the center through these points of division, and continued to the line r s, will divide cach hour upon it into quarters.

In Fig. 2. we have the reprefentation of a A dial or portable dial, which may be eafily drawn on a *a card*. card, and carried in a pocket-book. The lines *a d*, *a b* and *b c* of the gnomon muft be cut quite through the card; and as the end *a b* of the gnomon is raifed occafionally above the plane of the dial, it turns upon the uncut line *c d* as on a hinge. The line dotted *A B* muft be flit quite through the card, and the thread muft be put through the flit, and have a knot tied behind, to keep it from being eafily drawn out. On the other end of this thread is a fmall plummet *D*, and on the middle of it a fmall bead for fhewing the time of the day.

To

To reftify this dial, fet the thread in the flit right against the day of the month, and firetch the thread from the day of the month over the angular point where the curve lines meet at XII; then flift the bead to that point on the thread, and the dial will be reftified.

To find the hour of the day, raife the gnomon (no matter how much or how little) and hold the edge of the dial next the gnomon towards the fun, fo as the uppermost edge of the fhadow of the gnomon may just cover the *fhadow-line*; and the bead then playing freely on the face of the dial, by the weight of the plummet, will fhew the time of the day among the hour-lines, as it is forenoon or afternoon.

To find the time of fun-rifing and fetting, move the thread among the hour-lines, until it either covers fome one of them, or lies parallel betwixt any two; and then it will cut the time of fun-rifing among the forenoon hours, and of fun-fetting among the afternoon hours, on that day of the year for which the thread is fet in the fcale of months.

To find the fun's declination, ftretch the thread from the day of the month over the angular point at XII, and it will cut the fun's declination, as it is north or fouth, for that day, in the arched fcale of north and fouth declination.

To find on what days the fun enters the figns: when the bead, as above rectified, moves along any of the curve lines which have the figns of the zodiac marked upon them, the fun enters those figns on the days pointed out by the thread in the fcale of months.

The conftruction of this dial is very eafy, especially if the reader compares it all along with

with Fig. 3. as he reads the following explanation of that figure.

Draw the occult line A B parallel to the top of Fig. 3. the card, and crofs it at right angles with the fix o'clock line E C D; then upon C, as a center, with the radius CA, defcribe the femicircle AEL, and divide it into 12 equal parts (beginning at A) as Ar, As, &c. and from these points of division, draw the hour-lines r, s, t, u, v, E, w, and x, all parallel to the fix o'clock line E C. If each part of the femicircle be fubdivided into four equal parts, they will give the half-hour lines and quarters, as in Fig. 2. Draw the right line AS Do, making the angle SAB equal to the latitude of your place. Upon the center A defcribe the arch RST, and fet off upon it the arcs S R and ST, each equal to $23\frac{1}{2}$ degrees, for the fun's greatest declination; and divide them into 231 equal parts, as in Fig. 2. Through the interfection D of the lines ECD and ADo, draw the right line F D G at right angles to ADo. Lay a ruler to the points A and R, and draw the line A R F through $23\frac{1}{2}$ degrees of fouth declination in the arc SR; and then laying the ruler to the points A and T, draw the line ATG through 23' degrees of north declination in the arc ST: fo shall the lines ARF and A T G cut the line F D G in the proper length for the scale of months. Upon the center D, with the radius D F, defcribe the femicircle FoG; and divide it into fix equal parts, Fm, m n. no, &c. and from these points of division draw the right lines m b, n i, p k, and q l, each parallel to o D. Then fetting one foot of the compasses in the point F, extend the other to A, and defcribe the arc AzH for the tropic of 19 : with the fame extent, fetting one foot in G, defcribe
the line of ϑ and \Rightarrow (where the circle touches) comes to the latitude of your place in the quadrant: then, turn the whole meridional plane BD, with its circle G, upon the horizontal plane A, until the edge of the fhadow of the circle falls precifely on the day of the month in the femicircle; and then, the meridional plane will be due north and fouth, the axis EF will be parallel to the axis of the world, and will caft a fhadow upon the true time of the day, among the hours on the circle.

N. B. As, when the inftrument is thus rectified, the quadrant and femicircle are in the plane of the meridian, fo the circle is then in the plane of the equinoctial. Therefore, as the fun is above the equinoctial in fummer (in nothern latitudes) and below it in winter; the axis of the femicircle will caft a fhadow on the hour of the day, on the upper furface of the circle, from the 20th of March to the 23d of September: and from the 23d of September, to the 20th of March, the hour of the day will be determined by the fhadow of the femicircle, upon the lower furface of the circle. In the former cafe, the fhadow of the circle falls upon the day of the month, on the lower part of the diameter of the femicircle; and in the latter cafe, on the upper part.

Fig. 5.

The method of laying down the months and figns upon the femicircle, is as follows. Draw the right line A C B, equal the diameter of the femicircle A D B, and crofs it in the middle at right angles with the line E C D, equal in length to A D B; then E C will be the radius of the circle F C G, which is the fame as that of the femicircle. Upon E, as a center, defcribe the circle F C G, on which fet off the arcs C b and C i, each equal to $2 3^{\frac{1}{2}}$ degrees, and divide them accordingly into that number, for the fun's declination.

clination. Then, laying the edge of a ruler over the center E, and allo over the fun's declination for every * fifth day of each month (as in the card dial) mark the points on the diameter AB of the femicircle from a to g, which are cut by the ruler; and there place the days of the months accordingly, anfwering the fun's declination. This done, fetting one foot of the compaffes in C, and extending the other to a or g, describe the semicircle abcdefg; which divide into fix equal parts, and through the points of division draw right lines, parallel to CD, for the beginning of the fines (of which one half are on one fide of the femicircle, and the other half on the other fide) and fet the characters of the figns. to their proper lines, as in the figure.

The following table fhews the fun's place and declination, in degrees and minutes, at the noon of every day of the fecond year after leap-year; which is a mean between those of leap-year itfelf, and the first and third years after. It is useful for inferibing the months and their days on fun-dials; and also for finding the latitudes of places, according to the methods preferibed after the table.

* The intermediate days may be drawn in by hand, if the fpaces be large enough to contain them,

To

346

To find the latitude of any place by observation.

The latitude of any place is equal to the elevation of the pole above the horizon of that place. Therefore it is plain, that if a flar was fixt in the pole, there would be nothing required to find the latitude, but to take the altitude of that flar with a good inftrument. But although there is no flar in the pole, yet the latitude may be found by taking the greateft and leaft altitude of any flar that never fets: for if half the difference between these altitudes be added to the leaft altitude, or fubtracted from the greateft, the fum or remainder will be equal to the altitude of the pole at the place of obfervation.

But becaufe the length of the night must be more than 12 hours, in order to have two fuch obfervations; the fun's meridian altitude and declination are generally made use of for finding the latitude, by means of its complement, which is equal to the elevation of the equinoctial above the horizon; and if this complement be fubtracted from 90 degrees, the remainder will be the latitude: concerning which, I think, the following rules take in all the various cafes.

1. If the fun has north declination, and is on the meridian, and to the fouth of your place, fubtract the declination from the meridian altitude (taken by a good quadrant) and the remainder will be the height of the equinoctial or complement of the latitude north.

EXAM,

EXAMPLE.

Suppose { The fun's meridian altitude 42° 20' South And his declination, fubt. 10 15 North

Rem. the comp	lement	of the	lat.	32	5
which jubtract	from	and a	-	90	0

And the remainder is the latitude 57 55 North

2. If the fun has fouth declination, and is fouthward of your place at noon, add the declination to the meridian altitude; the fum, if lefs than 90 degrees, is the complement of the latitude north: but if the fum exceeds 90 degrees, the latitude is fouth; and if 90 be taken from that fum, the remainder will be the latitude.

EXAMPLES.

The fun's meridian altitude — The fun's declination, add —	65° 15	10' 30	South South
Complement of the latitude Subtract from	80 90	40	i si si
Remains the latitude	9	20	North
The fun's meridian altitude The fun's declination, add	80° 20	40' 10	South South
The fum isI	00	50 0	
Remains the latitude 🗕 🕳	10	50	South. 3. If

3. If the fun has north declination, and is on the meridian north of your place, add the declination to the north meridian altitude; the fum, if lefs than 90 degrees, is the complement of the latitude fouth: but if the fum is more than 90 degrees, fubtract 90 from it, and the remainder is the latitude north.

EXAMPLES.

Sun's meridian altitude —	60°	30' North
Sun's declination, add —	20	10 North
Complement of the latitude -	80	40
Subtract from	90	0
Remains the latitude	9	20 South
Sun's meridian altitude	70°	20' North
Sun's declination, add	23	20 North
The fum is	93	40
From which fubtract	90	0
Remains the latitude		In North

4. If the fun has fouth declination, and is north of your place at noon, fubtract the declination from the north meridian altitude, and the remainder is the complement of the latitude fouth.

EXAM-

EXAMPLE.

Sun's meridian altitude -	 50°	30'	North
Sun's declination, fubtract	20	10	South
Complement of the latitude Subtract this from	32 90	20 0	

And the remainder is the latitude 57 40 South

5. If the fun has no declination, and is fouth of your place at noon, the meridian altitude is the complement of the latitude north : but if the fun be then north of your place, his meridian altitude is the complement of the latitude fouth.

EXAMPLES.

Sun's meridian altitude Subtract from	38° 90	30'	South
Remains the latitude	51	30	North
Sun's meridian altitude Subtract from	38° 90	30'	North
Remains the latitude	51	30	South,

Actuality the latitude - - 51 30 South.

6. If you obferve the fun beneath the pole, fubtract his declination from 90 degrees, and add the remainder to his altitude; and the fum is the latitude.

EXAM-

EXAMPLE.

Sun's declination	20° 90	30
Remains Sun's altitude below the pole -	69 10	30 20 } add
The fum is the latitude	79	50.

Which is north or fouth, according as the fun's declination is north or fouth : for when the fun has fouth declination, he is never feen below the north pole; nor is he ever feen below the fouth pole, when his declination is north.

7. If the fun be in the zenith at noon, and at the fame time has no declination, you are then under the equinoctial, and fo have no latitude.

8. If the fun be in the zenith at noon, and has declination, the declination is equal to the latitude, north or fouth. These two cases are fo plain, that they require no examples.

LECT. XL

Of Dialing.

H AVING fhewn in the preceding Lecture how to make fun-dials by the affiftance of a good globe, or of a dialing fcale, we fhall now proceed to the method of conftructing dials arithmetically; which will be more agreeable to those who have learnt the elements of trigo-

trigonometry, becaufe globes and fcales can never be fo accurate as the logarithms, in finding the angular diftances of the hours. Yet, as a globe may be found exact enough for fome other requifites in dialing, we fhall take it in occafionally.

The construction of fun-dials on all planes whatever, may be included in one general rule: intelligible, if that of a horizontal dial for any given latitude be well underftood. For there is no plane, however obliquely fituated with refpect to any given place, but what is parallel to the horizon of fome other place; and therefore, if we can find that other place by a problem on the terrefirial globe, or by a trigonometrical calculation, and construct a horizontal dial for it; that dial, applied to the plane where it is to ferve, will be a true dial for that place .- Thus, an erect direct fouth dial in 51 the degrees north latitude, would be a horizontal dial on the fame meridian, 90 degrees fouthward of 512 degrees north latitude ; which falls in with 38 degrees of fouth latitude. but if the upright plane declines from facing the fourh at the given place, it would still be a horizontal plane 90 degrees from that place; but for a different longitude : which would alter the reckoning of the hours accordingly.

CASE I.

1. Let us fuppofe that an upright plane at London declines 36 degrees weftward from facing the fouth; and that it is required to find a place on the globe, to whole horizon the faid plane is parallel; and also the difference of longitude between London and that place.

Rectify

Rectify the globe to the latitude of London. and bring London to the zenith under the brafs meridian, then that point of the globe which lies in the horizon at the given degree of declination (counted weftward from the fouth point of the horizon) is the place at which the above-mentioned plane would be horizontal .- Now, to find the latitude and longitude of that place, keep your eye upon the place, and turn the globe eaftward, until it comes under the graduated edge of the brafs meridian ; then, the degree of the brafs meridian that flands directly over the place, is its latitude ; and the number of degrees in the equator, which are intercepted between the meridian of London and the brais meridian, is the place's difference of longitude.

Thus, as the latitude of London is 512 degrees north, and the declination of the place is 26 degrees weft; I elevate the north pole 51; degrees above the horizon, and turn the globe until London comes to the zenith, or under the graduated edge of the meridian; then, I count 36 degrees on the horizon westward from the fouth point, and make a mark on that place of the globe over which the reckoning ends, and bringing the mark under the graduated edge of the brafs meridian, I find it to be under 304 degrees in fouth latitude: keepingit there, I count in the equator the number of degrees between the meridian of London and the brasen meridian (which now becomes the meridian of the required place) and find it to be 423. Therefore an upright plane at London, declining 36 degrees weftward from the fouth, would be a horizontal plane at that place, whose latitude is 30 + degrees fouth of the equator, and longitude 423 degrees welt of the meridian of London.

Which

Which difference of longitude being converted into time, is 2 hours 51 minutes.

The vertical dial declining weftward 36 degrees at London, is therefore to be drawn in all respects as a horizontal dial for south latitude $30\frac{1}{4}$ degrees; fave only, that the reckoning of the hours is to anticipate the reckoning on the horizontal dial, by 2 hours 51 minutes: for so much soner will the sum come to the meridian of London, than to the meridian of any place whose longitude is $42\frac{3}{4}$ degrees west from London.

2. But to be more exact than the globe will fhew us, we fhall use a little trigonometry.

Let N E S W be the horizon of London, plate whole zenith is Z, and P the north pole of the XXIII. fphere; and let Z b be the polition of a vertical Fig. 1. plane at Z, declining weftward from S (the fouth) by an angle of 36 degrees; on which plane an erect dial for London at Z is to be defcribed. Make the femidiameter Z D perpendicular to Z b, and it will cut the horizon in D, 36 degrees weft of the fouth S. Then, a plane in the tangent H D, touching the fphere in D, will be parallel to the plane Z b; and the axis of the fphere will be equally inclined to both thefe planes.

Let $W \mathcal{Q} E$ be the equinoctial, whofe elevation above the horizon of Z (London) is $38\frac{1}{2}$ degrees; and P R D be the meridian of the place D, cutting the equinoctial in R. Then, it is evident, that the arc R D is the latitude of the place D (where the plane Z b would be horizontal) and the arc R \mathcal{Q} is the difference of longitude of the planes Z b and D H.

In the fpherical triangle WDR, the arc WDis given, for it is the complement of the plane's 6 decli-

declination from S the fouth; which complement is 54° (viz. $90^{\circ}-36^{\circ}$:) the angle at R; in which the meridian of the place D cuts the equator, is a right angle; and the angle RWDmeafures the elevation of the equinoctial above the horizon of Z, namely, $38\frac{1}{2}$ degrees. Say therefore, as radius is to the co-fine of the plane's declination from the fouth, fo is the cofine of the latitude of Z to the fine of RD the latitude of D: which is of a different denomination from the latitude of Z, becaufe Z and D are on different fides of the equator.

As radius - To co-fine So co-fine	$36^{\circ} \circ = RQ$ $51^{\circ} 30 = QZ$	10.00000 9.90796 9.79415
To fine 30°	14 = DR	(9.70211) =
he latitude of	D, whole horizon	is parallel to

N. B. When radius is made the first term, it may be omitted, and then, by subtracting it mentally from the sum of the other two, the operation will be shortened. Thus, in the prefent case,

To the logarithmic fine of $WR = 54^{\circ}$ of 9.90796 Add the logarithmic fine of $RD = 738^{\circ}$ 30' 9.79415

Their fum—radius - 9.70211 gives the fame folution as above. And we fhall keep to this method in the following part of the work.

To

* The co-fine of 36° o', or of $R \mathcal{Q}$. † The co-fine of 51° 30', or of $\mathcal{Q} Z$.

2

To find the difference of longitude of the places D and Z, fay, as radius is to the co-fine of $38\frac{1}{2}$ degrees, the height of the equinoctial at Z, fo is the co-tangent of 36 degrees, the plane's declination, to the co-tangent of the difference of longitudes. Thus,

To the logarithmic fine of * 51° 30' 9.89354 Add the logarithmic tang. of + 54° 0' 10.13874

Their fum—radius - - - - 10.03228 is the neareft tangent of $47^{\circ} 8' = W R$; which is the co-tangent of $42^{\circ} 52' = R Q$, the difference of longitude fought. Which difference, being reduced to time, is 2 hours $51\frac{1}{2}$ minutes.

3. And thus having found the exact latitude and longitude of the place D, to whose horizon the vertical plane at Z is parallel, we shall proceed to the construction of a horizontal dial for the place D, whose latitude is 30° 14' fouth; but anticipating the time at D by 2 hours 51 minutes (neglecting the $\frac{1}{2}$ minute in practice) because D is so far westward in longitude from the meridian of London; and this will be a true vertical dial at London, declining westward 36 degrees.

Affume any right line C S L for the fubfile Fig. 2. of the dial, and make the angle K C P equal to the latitude of the place (viz. 30° 14') to whole horizon the plane of the dial is parallel; then C R P will be the axis of the ftile, or edge that cafts the fhadow on the hours of the day, in the dial. This done, draw the contingent line E Q, cutting the fubfilar line at right angles in K;

* The co-fine of 38° 30', or of W D R, † The co-tangent of 36°, or of D W.

Aa

and

and from K make K R perpendicular to the axis C R P. Then K G (= K R) being made radius, that is, equal to the chord of 60' or tangent of 45° on a good fector, take 42° 52' (the difference of longitude of the places Z and D) from the tangents, and having fet it from K to M. draw C M for the hour-line of XII. Take K N equal to the tangent of an angle lefs by 15 degrees than KM; that is, the tangent 27° 52'; and through the point N draw C N for the hourline of I. The tangent of 12° 52' (which is 15° lefs than 27° 52') fet off the fame way, will give a point between K and N, through which the hour-line of II is to be drawn. The tangent of 2° 8' (the difference between 45° and 42° 52') placed on the other fide of C L, will determine the point through which the hour-line of III is to be drawn: to which 2° 8', if the tangent of 15° be added, it will make 17° 8'; and this fet off from K towards Q on the line $E \mathcal{Q}$, will give the point for the hour-line of IV: and fo of the reft .- The forenoon hourlines are drawn the fame way, by the continual addition of the tangents 15°, 30°, 45°, &c. to 42° 52' (=the tangent of K M) for the hours of XI, X, IX, &c. as far as necessary; that is, until there be five hours on each fide of the fubstile. The fixth hour, accounted from that hour or part of the hour on which the fubftile falls, will be always in a line perpendicular to the fubfile, and drawn through the center C.

4. In all erect dials, C M, the hour-line of XII, is perpendicular to the horizon of the place for which the dial is to ferve: for that line is the interfection of a vertical plane with the plane of the meridian of the place, both which are perpendicular to the plane of the horizon:

horizon: and any line HO, or bo, perpendicular to CM, will be a horizontal line on the plane of the dial, along which line the hours may be numbered: and CM being fet perpendicular to the horizon, the dial will have its true pofition.

5. If the plane of the dial had declined by an equal angle toward the eaft, its defcription would have differed only in this, that the hour-line of XII would have fallen on the other fide of the fubftile CL, and the line HO would have a fubcontrary polition to what it has in this figure.

6. And thefe two dials, with the upper points of their fliles turned toward the north pole, will ferve for the other two planes parallel to them; the one declining from the north toward the eaft, and the other from the north toward the weft, by the fame quantity of angle. The like holds true of all dials in general, whatever be their declination and obliquity of their planes to the horizon.

CASE II.

7. If the plane of the dial not only declines, Fig. 3. but also reclines, or inclines. Suppose its declination from fronting the fouth S be equal to the arc S D on the horizon; and its reclination be equal to the arc D d of the vertical circle D Z: then it is plain, that if the quadrant of altitude Z d D, on the globe, cuts the point D in the horizon, and the reclination is counted upon the quadrant from D to d; the interfection of the hour-circle P R d, with the equinoctial $W \mathcal{D} E$, will determine R d, the latitude of the place d, A a 2 whofe

whole horizon is parallel to the given plane Zb at Z; and RQ will be the difference in longitude of the planes at d and Z.

Trigonometrically thus: let a great circle pafs through the three points W, d, E; and in the triangle W D d, right-angled at D, the fides W D and D d are given; and thence the angle D W d is found, and fo is the hypothenufe W d. Again, the difference, or the fum, of D W dand D W R, the elevation of the equinoctial above the horizon of Z, gives the angle d W R; and the hypothenufe of the triangle W R d was juft now found; whence the fides R d and W Rare found, the former being the latitude of the place d, and the latter the complement of R Q, the difference of longitude fought.

Thus, if the latitude of the place Z be 52° 10' north; the declination S D of the plane Z b (which would be horizontal at d) be 36° , and the reclination be 15° , or equal to the arc D d; the fouth latitude of the place d, that is, the arc R d, will be 15° 9'; and R Q, the difference of the longitude, 36° 2'. From these data, therefore, let the dial (Fig. 4.) be deforibed, as in the former example.

8. Only it is to be observed, that in the reclining or inclining dials, the horizontal line will not fland at right angles to the hour-line of XII, as in erect dials; but its position may be found as follows.

Fig. 4.

To the common fubfiliar line C K L, on which the dial for the place d was defcribed, draw the dial C r p m 12 for the place D, whofe declination is the fame as that of d (viz. the arc S D; and HO, perpendicular to C m, the hourline of XII on this dial, will be a horizontal line on the dial C P R M XII. For the declination of

of both dials being the fame, the horizontal line remains parallel to itfelf, while the erect position of one dial is reclined or inclined with respect to the position of the other.

Or, the polition of the dial may be found by applying it to its plane, fo as to mark the true hour of the day by the fun, as fhewn by another dial; or by a clock, regulated by a true meridian line and equation table.

9. There are feveral other things requifite in the practice of dialing; the chief of which I fhall give in the form of arithmetical rules, fimple and eafy to thofe who have learnt the elements of trigonometry. For in practical arts of this kind, arithmetic fhould be ufed as far as it can go; and fcales never trufted to, except in the final conftruction, where they are abfolutely neceffary in laying down the calculated hourdiftances on the plane of the dial. And although the inimitable artifts of this metropolis have no occafion for fuch inftructions, yet they may be of fome ufe to ftudents, and to private gentlemen who amufe themfelves this way.

RULE I.

To find the angles which the hour-lines on any dial make with the fubfile.

To the longarithmic fine of the given latitude, or of the file's elevation above the plane of the dial, add the logarithmic tangent of the hour * diffance from the meridian, or from the

* That is, of 15, 30, 45, 60, 75°, for the hours of I, II, III, IV, V in the afternoon: and XI, X, IX, VIII, VII in the forenoon.

Aa 3

1

fub-

+ fubstile; and the fum minus radius will be the logarithmic tangent of the angle fought.

For, in Fig. 2. KC is to KM in the ratio compounded of the ratio of KC to KG (=KR) and of KG to KM; which, making CK the radius, 10,000000, or 10,0000, or 10, or 1, are the ratio of 10,000000, or of 10,0000, or of 10, or of 1, to $KG \times KM$.

Thus, in a horizontal dial, for latitude 51° 30', to find the angular diffance of XI in the forenoon, or I. in the afternoon, from XII.

To the logarithmic fine of 51 30' 9.89354 ‡ Add the logarithmic tang, of 15° 0' 9.42805

The fum—radius is - - 9.32159 = the logarithmic tangent of 11° 50′, or of the angle which the hour-line of XI or I makes with the hour of XII.

And by computing in this manner, with the fine of the latitude, and the tangents of 30, 45, 60, and 75°, for the hours of II, III, IV, and V in the afternoon; or of X, IX, VIII, and VII in the forenoon; you will find their angular diftances from XII to be 24° 18', 38° 3', 53° 35', and 71° 6'; which are all that there is occasion to compute for.—And these diftances may be set off from XII by a line of chords; or rather, by taking 1000 from a scale of equal parts, and setting that extent as a radius from C to XII; and then, taking 209 of

+ In all horizontal dials, and erect north or fouth dials, the fubfile and meridian are the fame: but in all declining dials, the fubfile line makes an angle with the meridian. \pm In which cafe, the radius C K is furnefed to be this 1.

 \ddagger In which cafe, the radius C K is fuppofed to be divided into roocooo equal parts.

5

360

the

the fame parts (which, in the tables, are the natural tangent of 11° 50') and fetting them from XII to XI and to I, on the line b o, which Fig. 2. is perpendicular to C XII: and fo for the reft of the hour-lines, which in the table of natural tangents, against the above diftances, are 451, 782, 1355, and 2920, of fuch equal parts from XII, as the radius C XII contains 1000. And laftly, fet off 1257 (the natural tangent of 51° 30') for the angle of the flile's height, which is equal to the latitude of the place.

The reafon why I prefer the use of the tabular numbers, and of a fcale decimally divided, to that of the line of chords, is becaufe there is the leaft chance of miltake and error in this way; and likewife, becaufe in fome cafes it gives us the advantage of a nonius' division.

In the univerfal ring-dial, for inftance, the divisions on the axis are the tangents of the angles, of the fun's declination placed on either fide of the center. But inftead of laying them down from a line of tangents, I would make a scale of equal parts, whereof 1000 should anlwer exactly to the length of the femi-axis, from the center to the infide of the equinoctial ring; and then lay down 434 of these parts toward each end from the center, which would limit all the divisions on the axis, because 434 are the natural tangent of 23° 29'. And thus by a nonius affixed to the fliding piece, and taking the fun's declination from an' Ephemeris, and the tangent of that declination from the table of natural tangents, the flider might be always fet true to within two minutes of a degree.

And this scale of 434 equal parts might be placed right against the 231 degrees of the fun's declination, on the axis, instead of the fun's Aa4

place,

place, which is there of very little ufe. For then, the flider might be fet in the ufual way, to the day of the month, for common ufe; but to the natural tangent of the declination, when great accuracy is required.

The like may be done wherever a fcale of fines or tangents is required on any inftrument.

RULE II.

The latitude of the place, the fun's declination, and bis hour diftance from the meridian, being given; to find (1.) his altitude; (2.) his azimuth.

Fig. 3.

1. Let d be the fun's place, dR, his declination; and in the triangle PZd, Pd the fum, or the difference, of dR, and the quadrant PRbeing given by the fuppolition, as allo the complement of the latitude PZ, and the angle dPZ, which measures the horary diffance of d from the meridian; we fhall (by Cafe 4. of *Keill's* Oblique fpheric Trigonometry) find the bafe Z d, which is the fun's diffance from the zenith, or the complement of his altitude.

And (2.) As fine Zd: fine Pd:: fine dPZ: dZP, or of its fupplement DZS, the azimuthal diffance from the fouth.

Or, the practical rule may be as follows.

Write A for the fine of the fun's altitude, Land l for the fine and co-fine of the latitude, Dand d for the fine and co-fine of the fun's declination, and H for the fine of the horary diftance from VI.

Then the relation of H to A will have three varieties.

I. When

1. When the declination is toward the elevated pole, and the hour of the day is between XII and VI; it is A = LD + Hld, and $H = \frac{A - LD}{Id}$.

2. When the hour is after VI, it is A = LD-Hld, and $H = \frac{LD+A}{Ld}$.

3. When the declination is toward the depressed pole, we have A = Hld - LD, and $H = \frac{d+LD}{ld}$.

Which theorems will be found uleful, and expeditious enough for folving those problems in geography and dialing, which depend on the relation of the fun's altitude to the hour of the day.

EXAMPLE. I.

Suppose the latitude of the place to be $51\frac{1}{2}$ degrees north; the time five hours diffant from XII, that is, an hour after VI in the morning, or before VI in the evening; and the fun's declination 20° north. Required the fun's altitude?

Then, to log. $L = \log$. fin. 51° 30′ 1.89354* add log. $D = \log$. fin. 20° o′ 1.534°5

Their fum - - - I.42759 gives L D =logarithm of 0.267664, in the natural fines.

* Here we confider the radius as unity, and not 10,00000, by which, inflead of the index 9 we have -1, as above: which is of no farther use, than making the work a little easier.

And,

And, to log. $H \equiv \log$. fin. $\pm 15^{\circ}$ or 1.41300 add $\begin{cases} \log l = \log l \text{ fin. } \pm 38^{\circ} \text{ or } 1.79414 \\ \log l = \log l \text{ fin. } \# 70^{\circ} \text{ or } 1.97300 \end{cases}$

Their fum - - - 1,18015 gives Hld =logarithm of 0. 151408, in the natural fines.

And thefe two numbers of (0.267664 and 0.151408) make $0.419072 \equiv A$; which, in the table, is the nearest natural fine of 24° 47, the fun's altitude fought.

The fame hour-diftance being affumed on the other fide of VI, then L D - Hld is 0.116256, the fine of 6° 40' $\frac{1}{2}$; which is the fun's altitude at V in the morning, or VII in the evening, when his north declination is 20°.

But when the declination is 20° fouth (or towards the deprefied pole) the difference Hld____ L D becomes negative, and thereby flew that, an hour before VI in the morning, or paft VI in the evening, the fun's center is 6° 40 $\frac{1}{2}$ below the horizon.

EXAMPLE. II.

In the fame latitude and north declination, from the given altitude to find the hour.

Let the altitude be 48° ; and because, in this case, $H = \frac{A-LD}{1d}$, and A (the natural fine of 48°)=.743145, and LD = .267664, A-LD

+ The diffance of one hour from VI.

The co-latitude of the place.

| The co-declination of the fun.

364

Will

will be 0.475481, whofe logarithmic

from which taking the logarithmic

fine of l + d = - - - - 1.7671354

Remains - - - - 1.9099977 the logarithmic fine of the hour-diftance fought, viz. of 54° 22'; which, reduced to time, is 3 hours $37\frac{1}{2}$ min. that is, IX h. $37\frac{1}{2}$ min. in the forenoon, or II h. $22\frac{1}{2}$ min. in the afternoon.

Put the altitude $= 18^{\circ}$, whofe natural fine is .3090170; and thence A-LD will be = .0491953; which divided by l + d, gives .0717179, the fine of 4° 6' $\frac{1}{2}$, in time 16 $\frac{1}{2}$ minutes nearly, before VI in the morning, or after VI in the evening, when the fun's altitude is 18°.

And, if the declination 20° had been towards the fouth pole, the fun would have been depreffed 18° below the horizon at $16\frac{1}{2}$ minutes after VI in the evening; at which time, the twilight would end; which happens about the 22d of November, and 19th of January, in the latitude of $51^{\circ}\frac{1}{2}$ north. The fame way may the end of twilight, or beginning of dawn, be found for any time of the year.

NOTE 1. If in theorem 2 and 3 (page 363) *A* is put = 0, and the value of *H* is computed, we have the hour of fun-rifing and fetting for any latitude, and time of the year. And if we put H = 0, and compute *A*, we have the fun's altitude or depression at the hour of VI. And lastly, if *H*, *A*, and *D* are given, the latitude may be found by the resolution of a quadratic equation; for $l = \sqrt{1 - L^2}$. 365

NOTE

NOTE 2. When A is equal o, H is equal $\frac{LD}{Id} = T L \times T D$, the tangent of the latitude multiplied by the tangent of the declination.

As, if it was required, what is the greatest

length of day in latitude 51° 30'? To the log. tangent of 51° 30' 0.0993948

Add the log. tangent of 23° 29' 1.6379563

Their fum - - - - -- 1.7373511 IS the log. fine of the hour-diftance 33° 7'; in time 2 h. 12 m. The longest day therefore is 12 h. + 4 h. 25 m. = 16 h. 25 m. And the fhortest day is 12 h. - 4 h. 25 m. = 7 h. 35 m.

And if the longest day is given, the latitude of the place is found ; $\frac{H}{TD}$ being equal to TL. Thus, if the longest day is $13\frac{1}{2}$ hours = 2×6 h. + 45 m. and 45 minutes in time being equal to 11 degrees.

From the log. fine of 11° 15' 1.2902357 Take the log. tang. of 23° 29' 1.6379562

Remains - -

- - 1.6522795 = the logarithmic tangent of lat. 24° 11'.

And the fame way, the latitudes, where the feveral geographical climates and parallels begin, may be found; and the latitudes of places, that are affigned in authors from the length of their days, may be examined and corrected.

NOTE 3. The fame rule for finding the longeft day in a given latitude, diffinguishes the hour-lines that are neceffary to be drawn on any dial from those which would be superfluous.

In lat. 52° 10' the longest day is 16 h. 32 m. and the hour-lines are to be marked from 44 m.

after

after III in the morning, to 16 m. after VIII in the evening.

In the fame latitude, let the dial of Art. 7. Fig. 4. be proposed; and the elevation of its file (or the latitude of the place d, whofe horizon is parallel to the plane of the dial) being 15° 9'; the longest day at d, that is, the longest time that the fun can illuminate the plane of the dial, will (by the rule $H = T L \times T D$) be twice 6 hours 27 minutes = 12 h. 54 m. The difference of longitude of the planes d and Z was found in the fame example to be 36° 2'; in time, 2 hours 24 minutes; and the declination of the plane was from the fouth towards the weft. Adding therefore 2 h. 24 min. to 5 h. 33 m. the earlieft fun-rifing on a horizontal dial at d, the fum 7 h. 57 m. fhews that the morning hours, or the parallel dial at Z, ought to begin at 3 men. before VIII. And to the lateft fun-fetting at d, which is 6 h. 27 m. adding the fame two h. 24 m. the fum 8 h. 51 m. exceeding 6 h. 16 m. the lateft fun-fetting at Z, by 35 m. fhews that none of the afternoon hour-lines are fuperfluous. And the 4 h. 13 m. from III h. 44 m. the fun rifing at Z to VII h: 57 m. the fun-riling at d, belong to the other face of the dial; that is, to a dial declining 36° from north to east, and inclining 15°.

EXAMPLE III.

From the fame data to find the fun's azimuth."

If H, L, and D are given, then (by Art, 2. of Rule II.) from H having found the altitude and its complement Zd; and the arc PD (the diftance

diftance from the pole) being given; fay, As the co-fine of the altitude is to the fine of the diftance from the pole, fo is the fine of the hourdiftance from the meridian to the fine of the azimuth diftance from the meridian.

Let the latitude be 51° 30° north, the declination 15° 9° fouth, and the time II h. 24 m. in the afternoon, when the fun begins to illuminate a vertical wall, and it is required to find the position of the wall.

Then, by the foregoing theorems, the complement of the altitude will be 81° $32^{\prime}\frac{1}{2}$, and P d the diffance from the pole being 109° 5', and the horary diffance from the meridian, or the angle d P Z, 36° .

101	og. fin. 7	74° 51'	-	-	1.98464
Add	log. lin.	36° o'	-	-	1.76922

When the altitude is given, find from thence the hour, and proceed as above.

This praxis is of fingular use on many occasions; in finding the declination of vertical planes more exactly than in the common way, especially if the transit of the fun's center is obferved by applying a ruler with fights, either plain or telescopical, to the wall or plane, whose declination is required.—In drawing a meridianline, and finding the magnetic variation.—In finding the bearings of places in terrestrial furveys; the transits of the fun over any place, or his horizontal diffance from it being observed, together with the altitude and hour.—And thence

thence determining small differences of longitude.-In observing the variation at fea, &c.

The learned Mr. Andrew Reid invented an inftrument feveral years ago, for finding the latitude at fea from two altitudes of the fun, obferved on the fame day, and the interval of the obfervations, measured by a common watch. And this inftrument, whose only fault was that of its being fomewhat expensive, was made by Mr. Jackfon. Tables have been lately computed for that purpose.

But we may often, from the foregoing rules, refolve the fame problem without much trouble; efpecially if we fuppofe the mafter of the fhip to know within 2 or 3 degrees what his latitude is. Thus.

Affume the two nearest probable limits of the latitude, and by the theorem $H = \frac{A+LD}{ld}$, compute the hours of observation for both suppositions. If one interval of those computed hours coincides with the interval observed, the question is folved. If not, the two diffances of the intervals computed, from the true interval, will give a proportional part to be added to, or subtracted from, one of the latitudes affumed. And if more exactness is required, the operation may be repeated with the latitude already found.

But whichever way the queftion is folved, a proper allowance is to be made for the difference of latitude arifing from the fhip's course in the time between the two observations.

Of

Of the double horizontal dial; and the Babyloman and Italian dials.

To the gnomonic projection, there is fometimes added a *ftereographic* projection of the hourcircles, and the parallels of the fun's declination, on the fame horizontal plane; the upright fide of the gnomon being floped into an edge, flanding perpendicularly over the center of the projection: fo that the dial, being in its due position, the fhadow of *that* perpendicular edge is a vertical circle passing through the fun, in the ftereographic projection.

The months being duly marked on the dial, the fun's declination, and the length of the day at any time, are had by infpection (as alfo his altitude, by means of a fcale of tangents). But its chief property is, that it may be placed true, whenever the fun fhines, without the help of any other inftrument.

Fig. 3.

Let d be the fun's place in the ftereographic projection, x dy z the parallel of the fun's declination, Z d a vertical circle through the fun's center, P d the hour-circle; and it is evident, that the diameter N S of this projection being placed doly north and fouth, these three circles will pass through the point d. And therefore, to give the dial its due position, we have only to turn its gnomon toward the fun, on a horizontal plane, until the hour on the common gnomonic projection coincides with that marked by the hour-circle P d, which passes through the interfection of the shadow Z d with the circle of the fun's prefent declination.

The Babylonian and Italian dials reckon the hours, not from the meridian, as with us, but from

from the fun's rifing and fetting. Thus, in Plate Italy, an hour before fun-fet is reckoned the 23d XXIII. hour; two hours before fun-fet, the 22d hour; and fo of the reft. And the fhadow that marks them on the hour-lines, is *that* of the point of a ftile. This occafions a perpetual variation between their dials and clocks, which they muft correct from time to time, before it arifes to any fenfible quantity, by fetting their clocks fo much fafter or flower. And in Italy, they begin their day, and regulate their clocks, not from fun-fet, but from about mid-twilight, when the Ave Maria is faid; which corrects the difference that would otherwife be between the clock and the dial.

The improvements which have been made in all forts of inftruments and machines for measuring time, have rendered such dials of little account. Yet, as the theory of them is ingenious, and they are really, in some respects, the best contrived of any for vulgar use, a general idea of their description may not be unacceptable.

Let Fig. 5. teprefent an erect direct fouth wall, on which a *Babylonian dial* is to be drawn, fhewing the hours from fun rifing; the latitude of the place, whofe horizon is parallel to the wall, being equal to the angle KCR. Make, as for a common dial KG = KR (which is perpendicular to CR) the radius of the equinoctial \mathcal{E} 2; and draw RS perpendicular to CK for the flile of the dial; the fhadow of whofe point R is to mark the hours, when SR is fet upright on the plane of the dial.

Then it is evident, that in the contingent line $\mathcal{I} \mathcal{Q}$, the fpaces K 1, K 2, K 3, &c. being taken equal to the tangents of the hour diffances from the meridian, to the radius KG, one, two, three, &c. hours after fun rifing, on the equinoctial day; the fhadow of the point R will be B b found,
Of Dialing.

length of a day is 14 equinoctial hours, the unequal hour is then $\frac{14}{12}$ or $\frac{7}{6}$ of an hour, that is, 70 minutes; and the nocturnal hour is 50 minutes. The first watch begins at VII (funlet); the fecond at three times 50 minutes after, viz. 1X h. 30 m. the third always at midnight; the morning watch at $\frac{1}{2}$ hour past II.

If it were required to draw a dial for fhewing these unequal hours, or 12th parts of the day, we must take as many declinations of the fun as are thought necessary, from the equator towards each tropic : and having computed the fun's altitude and azimuth for $\frac{1}{12}$, $\frac{2}{12}$, $\frac{3}{12}$ th parts, &c. of each of the diurnal arcs belonging to the declinations affumed : by these, the several points in the circles of declination, where the shadow of the flile's point falls, are determined : and curve lines drawn through the points of an homologous division will be the hour-lines required.

Of the right placing of dials, and having a true meridian line for the regulating of clocks and watches.

The plane on which the dial is to reft, being duly prepared, and every thing neceffary for fixing it, you may find the hour tolerably exact by a large equinoctial ring dial, and fet your watch to it. And then the dial may be fixed by the watch at your leifure.

If you would be more exact, take the fun's altitude by a good quadrant, noting the precife time of obfervation by a clock or watch. Then, compute the time for the altitude obferved, (by the rule, page 364) and fet the watch to agree with that time, according to the fun. A *Hadley*'s quadrant

How to make a Meridian Line.

quadrant is very convenient for this purpole; for, by it you may take the angle between the fun and his image, reflected from a balon of water: the half of which angle, fubtracting the refraction, is the altitude required. This is beft done in fummer, and the nearer the fun is to the prime vertical (the eafl or weft azimuth) when the observation is made, fo much the better.

Or, in fummer, take two equal altitudes of the fun in the fame day; one any time between 7 and 10 o'clock in the morning, the other between 2 and 5 in the afternoon; noting the moments of these two observations by a clock or watch: and if the watch shews the observations to be at equal distances from noon, it agrees exactly with the fun; if not, the watch must be corrected by half the difference of the forenoon and afternoon intervals; and then the dial may be fet true by the watch.

Thus, for example, fuppofe you have taken the fun's altitude when it was 20 minutes paft VIII in the morning by the watch; and found, by obferving in the afternoon, that the fun had the fame altitude io minutes before IIII; then it is plain, that the watch was 5 minutes too faft for the fun: for 5 minutes after XII is the middle time between VIII h. 20 m. in the morning, and III h. 50 m. in the afternoon; and therefore, to make the watch agree with the fun, it muft be fet back five minutes.

A good meridian line, for regulating clocks A merior watches, may be had by the following dian tane. method.

Make a round hole, almost a quarter of an inch diameter, in a thin plate of metal; and fix the plate in the top of a fouth window, in fuch a

B b. 3

manner_

How to make a Meridian Line.

manner, that it may recline from the zenith at an angle equal to the co-latitude of your place, as nearly as you can guefs; for then, the plate will face the fun directly at noon on the equinoctial days. Let the fun thine freely through the hole into the room; and hang a plumb-line to the ceiling of the room; at leaft five or fix feet from the window, in fuch a place as that the fun's rays, tranfmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the faid place on the ceiling, take away the line.

Having adjufted a fliding bar to a dove-tail groove, in a piece of wood about 18 inches long, and fixed a hook into the middle of the bar, nail the wood to the above-mentioned place on the cieling, parallel to the fide of the room in which the window is: the groove and bar being towards the floor. Then, hang the plumb-line upon the hook in the bar, the weight or plummet reaching almost to the floor; and the whole will be prepared for farther and proper adjustment.

This done, find the true folar time by either of the two laft methods, and thereby regulate. your clock. Then, at the moment of next noon by the clock, when the fun fhines, move the fliding bar in the groove until the fhadow of the plumb-line bifects the image of the fun (made by his rays transmitted through the hole) on the floor, wall, or on a white forcen placed on the north fide of the line; the plummet or weight at the end of the line hanging freely in a pail of water placed below it on the floor.—But becaufe this may not be quite correct for the first time, on account that the plummet will not fettle immediately, even in water; it may be farther corrected

rected on the following days, by the above method, with the fun and clock; and fo brought to a very great exactnefs.

N.B. The rays transmitted through the hole, will cast but a faint image of the fun, even on a white fcreen, unlefs the room be fo darkened that no fun-thine may be allowed to enter, but what comes through the fmall hole in the plate. And always, for fome time before the observation is made, the plummet ought to be immerfed in a jar of water, where it may hang freely; by which means the line will foon become iteady, which otherwife would be apt to continue fwinging.

As this meridian line will not only be fufficient for regulating of clocks and watches to the true time by equation tables, but alfo for most aftronomical purposes, I shall fay nothing of the magnificent and expensive meridian lines at *Bologna* and *Rome*, nor of the better methods by which aftronomers observe precisely the transits of the heavenly bodies on the meridian.

LECT. XII.

Shewing how to calculate the mean time of any New or Full Moon, or Ecliple, from the creation of the world to the year of CHRIST 5800.

IN the following tables, the mean lunation is about a 20th part of a fecond of time longer than its measure as now printed in the third edition of my Aftronomy; which makes a difference of an hour and 30 minutes in 8000 years.—But this is not material, when only the mean times are required.

Bb4 PRE-

EXAMPLE I.

Required the time of new moon in September, 1764? (a year not inferted in the table)

A those in our In the later when	Moo.	n fre	om	fun.
To the year after Christ's	8	p		"
birth 1753	10	9	24	56

fub.	n coor ni yn	I	0	57
And the remainder will be Next less mean mot. for 2 min.			I	5
fub	-	-	I	I
Remains the mean mot. of 12 fec				4

These times, being collected, would shew the mean time of the required new moon in September 1764, to be on the 26th day, at 2 hours 2 min. 12 sec. past noon. But, as it is in a leap-year, and after February, the time is one day too late. So, the true mean time is September the 25th, at 2 m. 12 sec. past II in the afternoon.

N. B.

N. B. The tables always begin the day at noon, and reckon thenceforward, to the noon of the day following.

To find the mean time of full moon in any given year and month after the Christian Æra.

Having collected the moon's mean motion from the fun for the beginning of the given year and month, and fubtracted their fum from 12 figns (as in the former example) add 6 figns to the remainder, and then proceed in all refpects as above.

EXAMPLE II.

Required the mean time of full moon in September 1764?

	Moo	n fr	om	ſun.
To the year after Christ's		0		"
birth 1753	10	'9	24	56

Remains the mean mot. for 8 fec. - - - -

So, the mean time, according to the tables, is the 11th of September, at 7 hours 40 minutes 8 feconds paft noon. One day too late, being after February in a leap year.

And thus may the mean time of any new or full moon be found, in any year after the Chriftian Æra.

To find the mean time of new or full moon in any given year and month before the Christian Æra.

If the given year before the year of CHRIST 1 be found in the third column of the table, under the title *Years before and after* CHRIST, write it out, together with the given month, and join the mean motions. But, if the given year be not in the table, take out the next greater one to it that you find; which being ftill farther back than the given year, add as many compleat years to it as will bring the time forward to the given year; then join the month, and proceed in all refpects as above.

EXAM-

EXAMPLE III.

Required the mean time of new moon in May, the year before Ckrift 585?

The next greater year in the table is 600; which being 15 years before the given year, add the mean motions for 15 years to those of 600, together with those for the beginning of May.

Moon from fun.

To the year before <i>Chrift</i> 600 - Add compleat years motion 15 And the mean motions for May	56 0	11 0 22	6 53 53	16 24 23

fubt		I	31	26
And the remainder will be - Next lefs mean mot. for 3 min.			I	37
fubt		76-	I	31
Rem. the mean mot. of 14 fe- conds	•			6
MARS				So,

The Calculation of Eclipfes.

So, the mean time by the tables, was the 29th of May, at 3 hours 3 min. 14 fec. paft noon. A day later than the truth, on account of its being in a leap-year. For as the year of CHRIST I was the first after a leap-year, the year 585 before the year I was a leap-year of courfe.

If the given year be after the Christian Æra, divide its date by 4, and if nothing remains, it is a leap-year in the old stile. But if the given year was before the Christian Æra (or Year of CHRIST 1) subtract one from its date, and divide the remainder by 4; then, if nothing remains, it was a leap-year; otherwise not.

To find whether the fun is eclipfed at the time of any given change, or the moon at any given full.

Ofeclipses.

From the Table of the fun's mean motion (or diftance) from the moon's afcending node, collect the mean motions answering to the given time; and if the refult shews the fun to be within 18 degrees of either of the nodes at the time of new moon, the fun will be eclipfed at that time. Or, if the refult shews the fun to be within 12 degrees of either of the nodes at the time of full moon, the moon will be eclipfed at that time, in or near the contrary node; otherwise not.

EXAM

The Calculation of Eclipfes.

EXAMPLE IV.

The moon changed on the 26th of September 1764, at 2 b. 2 m. (neglecting the seconds) after noon (See Example I.) Qu. Whether the sun was eclipsed at that time?

To th	e year after Christ's	Sun *	fron	n no	de.	
birt	h	I	28	0	19	
nuu	compleat years -	7	2	3	56	
	(fum)	(764)			9.	
1	September -	(i, it)	8	I 2	22	49
And a	20 days .	•	adati	27	0	13
P.S. 7	2 nours -	1.1			5	12
1994	z minutes -					5
Sun's	diffance from the	alcond	11-0	-	-	

ing node

6 9 32 34

Now, as the defcending node is just opposite to the afcending, (viz. 6 figns diftant from it) and the tables fhew only how far the fun has gone from the afcending node, which, by this example, appears to be 6 figns 9 degrees 32 minutes 34 feconds, it is plain that he must have then been eclipfed; as he was then only 9° 32' 34''fhort of the defcending node.

To find when there must be Eclipses.

remainder, fubtract the next lefs mean motions belonging to whatever month you find them in the table; and from heir remainder fubtract the next lefs mean motion for days, and fo on for bours and minutes: the refult of all which will fhew the time of the fun's mean conjunction with the afcending node of the moon's orbit.

EXAMPLE VII.

Required the time of the fun's conjunction with the afcending node in the year 1764?

Sun from node. 5 0 To the year after Christ's birth 1753 1 28 0 19 Add compleat years II 7 2 3 56 Mean dift at beg. of A.D. 1764 9 0 4 15 Subtract this diffance from a circle, or 12 0 0 0 And there remains 2 29 55 45 Next lefs mean motion for March, fubtract 2 1 16 39 And the remainder will be 0 28 39 6 Next lefs mean motion for 27 days, fubtract 0 28 2 32 And there remains 36 34 Next lefs mean motion for 14 hours, subtracted 36 21 Remains (nearly) the mean motion of 5 minutes I3

Hence

The Period and Return of Eclipfes.

Hence it appears, that the fun will pafs by the moon's afcending node on the 27th of March, at 14 hours 5 minutes paft noon; viz. on the 28th day, at 5 minutes paft II in the morning, according to the tables: but this being in a leap-year, and after February, the time is one day too late. Confequently, the true time is at 5 min. paft II in the morning on the 27th day; at which time, the defcending node will be directly oppofite to the fun.

If 6 figns be added to the remainder arifing from the first subtraction, (viz. from 12 figns) and then the work carried on as in the last example, the result will give the mean time of the fun's conjunction with the descending node. Thus, in

EXAMPLE VIII.

To find when the fun will be in conjunction with the defeending node in the year 1764?

Rem. (nearly) the mean mot. of	111			

So that, according to the tables, the fun will be in conjunction with the *descending node* on the 16th of September, at 21 hours 31 minutes paft noon: one day later than the truth, on account of the leap-year.

I 20

The limits of eclipfes.

Their period and reflitution.

When the moon changes within 18 days before or after the fun's conjunction with either of the nodes, the fun will be eclipfed at that change : and when the moon is full within 12 days before or after the time of the fun's conjunction with either of the nodes, fhe will be eclipfed at that full : otherwife not.

If to the mean time of any eclipfe, either of the fun or moon, we add 557 Julian years 21 days 18 hours 11 minutes and 51 feconds (in which there are exactly 6890 mean lunations) we fhall have the mean time of another eclipfe. For at the end of that time, the moon will be either new or full, according as we add it to the time of new or full moon; and the fun will be only 45'' farther from the fame node, at the end of 6 the

The Period and Return of Eclipses.

the faid time, than he was at the beginning of it; as appears by the following example*.

The period.	Moor	fr. fun.	Sun fi	r. node.

Mean motions -0 0 0 0 -0 0 0 45

And this period is to very near, that in 6000 years it will vary no more from the truth, as to the reftitution of eclipfes, than 8⁺/₄ minutes of a degree; which may be reckoned next to nothing. It is the fhorteft in which, after many trials, I can find fo near a conjunction of the fun, moon, and the fame node.

* Dr. HALLEY's period of eclipfes contains only 18 years 11 days 7 hours 43 minutes 20 feconds; in which time, according to his tables, there are juft 223 mean lunations: but, as in that time, the fun's mean motion from the node is no more than 11° 29° 31′ 49″, which wants 28′ 11″ of being as nearly in conjunction with the fame node at the end of the period as it was at the beginning; this period cannot be of constant duration for finding eclipfes, because it will in time fall quite without their limits. The following pables make this period 31 feconds florter, as appears by the following calculation.

The period.	Moon fr. Sun. Sun fr. node.

In leap years, after February, a day and its motion muft be added to the time for which the moon's mean diffance from the fun is given. But, when the mean time of any new or full moon is required in leap-year after February, a day muft be fubtracted from the mean time thereof, as found by the tables. In common years they give the day right.

Years

A Table of the Sun's mean Motion from the Moon's Ajcending Node.

MECHANICS.

The Description of a new and safe Crane, which has four different Powers, adapted to different Weights.

HE common crane confifts only of a large wheel and axle; and the rope, by which goods are drawn up from fhips, or let down from the quay to them, winds or coils round by the axle, as the axle is turned by men walking in the wheel. But, as these engines have nothing to ftop the weight from running down, if any of the men happen to trip or fall in the wheel, the weight defcends, and turns the wheel rapidly backward, and toffes the men violently about within it; which has produced melancholy inftances, not only of limbs Dd 2 broke,

broke, but even of lives loft, by this ill-judged conftruction of cranes. And befides, they have but one power for all forts of weights; io that they generally fpend as much time in raifing a fmall weight as in raifing a great one.

These imperfections and dangers induced me to think of a method of remedying them. And for that purpose, I contrived a crane with a proper stop to prevent the danger, and with different powers suited to different weights; so that there might be as little loss of time as posfible : and also, that when heavy goods are let down into ships, the descent may be regular and deliberate.

This crane has four different powers: and, I believe, it might be built in a room eight feet in width: the gib being on the outlide of the room.

Three trundles, with different numbers of ftaves, are applied to the cogs of a horizontal wheel with an upright axle; and the rope, that draws up the weight, coils round the axle. The wheel has 96 cogs, the largeft trundle 24 flaves, the next largest has 12, and the smallest has 6. So that the largeft trundle makes 4 revolutions for one revolution of the wheel; the next makes 8, and the fmalleft makes 16. A winch is occafionally put upon the axis of either of thefe trundles, for turning it; the trundle being then ufed that gives a power beft fuited to the weight: and the handle of the winch defcribes a circle in every revolution equal to twice the circumference of the axle of the wheel. So that the length

5

length of the winch doubles the power gained by each trundle.

As the power gained by any machine, or engine whatever, is in direct proportion as the velocity of the power is to the velocity of the weight; the powers of this crane are eafily effimated, and they are as follows.

If the winch be put upon the axle of the largeft trundle, and turned four times round, the wheel and axle will be turned once round : and the circle defcribed by the power that turns the winch, being, in each revolution, double the circumference of the axle, when the thicknefs of the rope is added thereto; the power goes through eight times as much fpace as the weight rifes through : and therefore (making fome allowance for friction) a man will raife eight times as much weight by the crane as he would by his natural ftrength without it : the power, in this cafe, being as eight to one.

If the winch be put upon the axis of the next trundle, the power will be as fixteen to one, becaufe it moves 16 times as faft as the weight moves.

If the winch be put upon the axis of the fmalleft trundle, and turned round; the power will be as 32 to one.

But, if the weight fhould be too great, even for this power to raife, the power may be doubled by drawing up the weight by one of the parts of a double rope, going under a pulley in the moveable block, which is hooked to the weight below the arm of the gib; and then the Dd_3 power

against the edge of the wheel U, and thereby hinder the too quick defcent of the weight; and will quite ftop the weight if pulled hard. And if the man who pulls the lever, fhould happen inadvertently to let it go; the elastic bar will fuddenly pull it up, and the catch will fall down and ftop the machine.

WW are two upright rollers above the axis or upper gudgeon of the gib E: their ufe is to let the rope C bend upon them, as the gib is turned to either fide, in order to bring the weight over the place where it is intended to be let down.

N. B. The rollers ought to be fo placed, that if the rope C be firetched close by their utmoft fides, the half thickness of the rope may be perpendicularly over the center of the upper gudgeon of the gib. For then, and in no other position of the rollers, the length of the rope between the pulley in the gib and the axle of the great wheel will be always the fame, in all positions of the gib: and the gib will remain in any position to which it is turned.

When either of the trundles is not turned by the winch in working the crane, it may be drawn off from the wheel, after the pin near the axis of the trundle is drawn out, and the thick piece of wood is raifed a little behind the outward fupporter of the axis of the trundle. But this is not material: for, as the trundle has no friction on its axis but what is occafioned by its weight, it will be turned by the wheel without any fenfible refistance in working the crane.

A Pyro-

A Pyrometer, that makes the Expansion of Metals by Heat visible to the five and forty thousandth Part of an Inch.

The upper furface of this machine is reprefented by Fig. 1. of Plate II. Its frame ABGD is made of mahogany wood, on which is a circle divided into 360 equal parts; and within that circle is another, divided into 8 equal parts. If the fhort bar E be pushed one inch forward (or toward the center of the circle) the index e will be turned 125 times round the circle of 360 parts or degrees. As 125 times 360 is 45,000, 'tis evident, that if the bar E be moved only the 45,000dth part of an inch, the index will move one degree of the circle. But as in my pyrometer, the circle is 9 inches in diameter, the motion of the index is visible to half a degree, which answers to the ninety thousandth part of an inch in the motion or pushing of the short bar E.

One end of a long bar of metal F is laid into a hollow place in a piece of iron G, which is fixed to the frame of the machine; and the other end of this bar is laid againft the end of the fhort bar E, over the fupporting crofs bar H i: and, as the end f of the long bar is placed clofe againft the end of the fhort bar, 'tis plain, that if F expands, it will pufh E forward, and turn the index e.

The machine flands on four fhort pillars, high enough from a table, to let a fpirit-lamp be put on the table under the bar F; and when that is done, the heat of the flame of the lamp expands the bar, and turns the index.

There

There are bars of different metals, as filver, brafs, and iron; all of the fame length as the bar F, for trying experiments on the different expansions of different metals, by equal degrees of heat applied to them for equal lengths of time; which may be measured by a pendulum, that fwings feconds. Thus,

Put on the brafs bar F, and fet the index to the 360th degree: then put the lighted lamp under the bar, and count the number of feconds in which the index goes round the plate, from 360 to 360 again; and then blow out the lamp, and take away the bar.

This done, put on an iron bar F where the brafs one was before, and then fet the index to the 360th degree again. Light the lamp, and put it under the iron bar, and let it remain juft as many feconds as it did under the brafs one; and then blow it out, and you will fee how many degrees the index has moved in the circle: and by that means you will know in what proportion the expansion of iron is to the expansion of brafs; which I find to be as 210 is to 360, or as 7 is to 12.—By this method, the relative expansions of different metals may be found.

The bars ought to be exactly of equal fize; and to have them to, they fhould be drawn, like wire, through a hole.

When the lamp is blown out, you will fee the index turn backward; which fhews that the metal contracts as it cools.

The infide of this pyrometer is conftructed as follows.

TI

In Fig. 2. Aa is the flort bar, which moves between rollers; and, on the fide a it has 15 teeth in an inch, which take into the leaves of a pinion B (12 in number) on whofe axis is the wheel C of 100 teeth, which take into the 10 leaves of the pinion D, on whofe axis is the wheel E of 100 teeth, which take into the 10 leaves of the pinion F, on the top of whofe axis is the index above mentioned.

Now, as the wheels C and E have 100 teeth each, and the pinions D and F have ten leaves each; 'tis plain, that if the wheel C turn once round, the pinion F and the index on its axis will turn 100 times round. But, as the first pinion B has only 12 leaves, and the bar A.athat turns it has 15 teeth in an inch, which is 12 and a fourth part more; one inch motion of the bar will caufe the last pinion F to turn an hundred times round, and a fourth part of an hundred over and above, which is 25. So that, if Aa be pushed one inch, F will be turned 125 times round.

A filk thread b is tied to the axis of the pinion D, and wound feveral times round it; and the other end of the thread is tied to a piece of flender watch-fpring G which is fixed into the ftud H. So that, as the bar f expands, and puffies the bar Aa forward, the thread winds round the axle, and draws out the fpring; and as the bar contracts, the fpring pulls back the thread, and turns the work the contrary way, which puffies back the flort bar Aa againft the long bar f. This fpring always keeps the teeth of the wheels in contact with the leaves of the thread to be added #### MECHANICS.

the pinions, and fo prevents any shake in the teeth.

In Fig. 1. the eight divisions of the inner circle are fo many thousandth parts of an inch in the expansion or contraction of the bars; which is just one thousandth part of an inch for each division moved over by the index.

A Water-Mill, invented by Dr. Barker, that has neither Wheel nor Trundle.

This machine is reprefented by Fig. 1. of Plate III. in which, A is a pipe or channel that brings water to the upright tube B. The water runs down the tube, and thence into the horizontal trunk C, and runs out through holes at d and e near the ends of the trunk on the contrary fides thereof.

The upright fpindle D is fixt in the bottom of the trunk, and fcrewed to it below by the nut g; and is fixt into the trunk by two crofs bars at f: fo that, if the tube B and trunk Cbe turned round, the fpindle D will be turned alfo.

The top of the fpindle goes fquare into the rynd of the upper mill-ftone H, as in common mills; and, as the trunk, tube, and fpindle turn round, the mill-ftone is turned round thereby. The lower, or quiefcent mill-ftone is reprefented by I; and K is the floor on which it refts, and wherein is the hole L for letting the meal

meal run through, and fall down into a trough which may be about M. The hoop or cafe that goes round the mill-ftone refts on the floor K, and fupports the hopper, in the common way. The lower end of the fpindle turns in a hole in the bridge-tree GF, which fupports the mill-ftone, tube, fpindle, and trunk. This tree is moveable on a pin at b, and its other end is fupported by an iron rod N fixt into it, the top of the rod going through the fixt bracket O, and having a fcrew-nut o upon it, above the bracket. By turning this nut forward or backward, the mill-ftone is raifed or lowered at pleafure.

Whilft the tube B is kept full of water from the pipe A, and the water continues to run out from the ends of the trunk; the upper millftone H, together with the trunk, tube, and fpindle turns round. But, if the holes in the trunk were ftopt, no motion would enfue; even though the tube and trunk were full of water. For,

If there were no hole in the trunk, the preffure of the water would be equal against all parts of its fides within. But, when the water has free egress through the holes, its preffure there is entirely removed: and the preffure against the parts of the fides which are opposite to the holes, turns the machine.

A Machine for demonstrating that, on equal Bottoms, the Preffure of Fluids is in Proportion to their perpendicular Heights, without any regard to their Quantities.

HIS is termed The Hydroftatical Paradox: and the machine for thewing it is reprefented in Fig. 2. of Plate III. In which A is a box that holds about a pound of water, $a \ b \ c \ d \ e$ a glafs-tube fixt in the top of the box, having a fmall wire within it; one end of the wire being hooked to the end F of the beam of a balance, and the other end of the wire fixt to a moveable bottom, on which the water lies, within the box; the bottom and wire being of equal weight with an empty fcale (out of fight in the figure) hanging at the other end of the balance. If this fcale be pulled down, the bottom will be drawn up within the box, and that motion will caufe the water to rife in the glafs-tube.

Put one pound weight into the fcale, which will move the bottom a little, and caufe the water to appear just in the lower end of the tube at a; which shews that the water prefices with the force of one pound on the bottom: put another pound into the fcale, and the water will rife from a to b in the tube, just twice as high above the bottom as it was when at a; and then, as its preffure on the bottom supports two pound weight in the scale, 'tis plain that the preffure on the bottom is then equal to two pounds. Put a third pound weight in the scale, and the 3

water will be raifed from b to c in the tube, three times as high above the bottom as when it began to appear in the tube at a; which shews, that the fame quantity of water that preffed, but with the force of one pound on the bottom, when raifed no higher than a, preffes with the force of three pounds on the bottom when raifed three times as high to c in the tube. Put a fourth pound weight into the scale, and it will cause the water to rife in the tube from c to d, four times as high as it was when it was all contained in the box, which fhews that its preffure then upon the bottom is four times as great as when it lay all within the box. Put a fifth pound weight into the fcale, and the water will rife in the tube from d to e, five times as high as it was above the bottom before it role in the tube ; which shews that its preffure on the bottom is then equal to five pounds, feeing that it fupports fo much weight in the scale. And so on, if the tube was still longer; for it would ftill require an additional pound put into the scale, to raife the water in the tube to an additional height equal to the fpace d e; even if the bore of the tube was fo fmall as only to let the wire move freely within it, and leave room for any water to get round the wire.

Hence we infer, that if a long narrow pipe or tube was fixed in the top of a cafk full of liquor, and if as much liquor was poured into the tube as would fill it, even though it were fo fmall as not to hold an ounce weight of liquor; the preffure arifing from the liquor in the tube would be as great upon the bottom, and

16

and be in as much danger of burfting it out, as if the cafk was continued up, in its full fize, to the height of the tube, and filled with liquor.

In order to account for this furprifing affair, we muft confider that fluids prefs equally in all manner of directions; and confequently that they prefs juft as ftrongly upward as they do downward. For, if another tube, as f, be put into a hole made into the top of the box, and the box be filled with water; and then, if water be poured in at the top of the tube $a \ b \ c \ d \ e$, it will rife in the tube f to the fame height as it does in the other tube: and if you leave off pouring, when the water is at c, or any other place in the tube $a \ b \ c \ d \ e$, you will find it juft as high in the tube, the fecond will be filled alfo.

Now it is evident that the water rifes in the tube f, from the downward preffure of the watep in the tube a b c d e, on the furface of the water, contiguous to the infide of the top of the box; and as it will ftand at equal heights in both tubes, the upward preffure in the tube f is equal to the downward preffure in the other tube. But, if the tube f were put in any other part of the top of the box, the rifing of the water in it would still be the fame : or, if the top was full of holes, and a tube put into each of them, the water would rife as high in each tube as it was poured into the tube abcde; and then the moveable bottom would have the weight of the water in all the tubes to bear, befides the weight of all the water in the box.

And

And feeing that the water is preffed upward into each tube, 'tis evident that, if they be all taken away, excepting the tube a b c d e, and the holes in which they flood be flopt up; each part, thus ftopt, will be preffed as much upward as was equal to the weight of water in each tube. So that, the upward preffure against the infide of the top of the box, on every part equal in breadth to the width of the tube abcde, will be preffed upward with a force equal to the whole weight of water in the tube. And confequently, the whole upward preffure against the top of the box, arising from the weight or downward preffure of the water in the tube, will be equal to the weight of a column of water of the fame height with that in the tube, and of the fame thickness as the width of the infide of the box : and this upward preffure against the top will re-act downward against the bottom, and be as great thereon, as would be equal to the weight of a column of water as thick as the moveable bottom is broad, and as high as the water stands in the tube. And thus, the paradox is folved.

The moveable bottom has no friction against the infide of the box, nor can any water get between it and the box. The method of making it fo, is as follows:

In Fig. 3. ABCD reprefents a fection of the box, and abcd is the lid or top thereof, which goes on tight, like the lid of a common paper fnuff-box. E is the moveable bottom, with a groove around its edge, and it is put into a bladder fg, which is tied close around it in the Ee groove 17

18

groove by a ftrong waxed thread; the bladder coming up like a purfe within the box, and put over the top of it at a and d all round, and then the lid prefied on. So that, if water be poured in through the hole ll of the lid, it will lie upon the bottom E, and be contained in the fpace f E g b within the bladder; and the bottom may be raifed by pulling the wire i, which is fixed to it at E: and by thus pulling the wire, the water will be lifted up in the tube k, and as the bottom does not touch againft the infide of the box, it moves without friction.

Now, fuppole the diameter of this round bettom to be three inches (in which cafe, the area thereof will be 9 circular inches) and the diameter of the bore of the tube to be a quarter of an inch; the whole area of the bottom will be 144 times as great as the area of the top of a pin that would fill the tube like a cork.

And hence it is plain, that if the moveable bottom be raifed only the 144th part of an inch, the water will thereby be raifed a whole inch in the tube; and confequently, that if the bottom be raifed one inch, it would raife the water to the top of a tube 144 inches, or 12 feet, in height.

N. B. The box must be open below the moveable bottom, to let in the air. Otherwife, the preffure of the atmosphere would be fo great upon the moveable bottom, if it be three inches in diameter, as to require 108 pounds in the fcale, to balance that preffure, before the bottom could begin to move.

A Machine,

A Machine, to be fulftituted in Place of the common Hydrostatical Bellows.

In Fig. 1. of PLATE IV. ABCD is an oblong fquare box, in one end of which is a round groove, as at a, from top to bottom, for receiving the upright glass tube I, which is bent to a right angle at the lower end (as at i in Fig. 2.) and to that part is tied the neck of a large bladder K, (Fig. 2.) which lies in the bottom of the box. Over this bladder is laid the moveable board L (Fig. 1. and 3.) in which is fixt an upright wire M; and leaden weights, NN, to the amount of 16 pounds, with holes in their middle, which are put upon the wire, over the board, and prefs upon it with all their force.

The crofs bar p is then put on, to fecure the tube from falling, and keep it in an upright polition: And then the piece E FG is to be put on, the part G fliding tight into the dove-tail'd groove H, to keep the weights NN horizontal, and the wire M upright; there being a round hole e in the part E F for receiving the wire.

There are four upright pins in the four corners of the box within, each almost an inch long, for the board L to reft upon; to keep it from preffing the fides of the bladder below it close together at first,

The whole machine being thus put together, pour water into the tube at top; and the water will run down the tube into the bladder below the board; and after the bladder has been $E e_2$ filled

filled up to the board, continue pouring water into the tube, and the upward preffure which it will excite in the bladder, will raife the board with all the weight upon it, even though the bore of the tube fhould be fo fmall, that lefs than an ounce of water would fill it.

This machine acts upon the fame principle, as the one laft defcribed, concerning the Hydroflatical paradox. For, the upward preffure against every part of the board (which the bladder touches) equal in area to the area of the bore of the tube, will be preffed upward with a force equal to the weight of the water in the tube; and the fum of all these preffures, against fo many areas of the board, will be fufficient to raife it with all the weights upon it.

In my opinion, nothing can exceed this fimple machine, in making the upward prefiure of fluids evident to fight.

The Caufe of reciprocating Springs, and of ebbing and flowing Wells, explained.

In Fig. 1. of PLATE V. Let abcd be a hill, within which is a large cavern AA near the top, filled or fed by rains and melted fnow on the top a, making their way through chinks and crannies into the faid cavern, from which proceeds a fmall ftream CC within the body of the hill, and iffues out in a fpring at G on the fide of the hill, which will run conftantly whilft the cavern is fed with water.

From the fame cavern A A, let there be a fmall channel D, to carry water into the cavern B;

21

B; and from that cavern let there be a bended channel E e F, larger than D, joining with the former channel CC, as at f before it comes to the fide of the hill: and let the joining at f be below the level of the bottom of both thefe caverns.

As the water rifes in the cavern B, it will rife as high in the channel E e F: and when it rifes to the top of that channel at e, it will run down the part e F G, and make a fwell in the fpring G, which will continue till all the water is drawn off from the cavern B, by the natural fyphon $E \, e \, F$, (which carries off the water fafter from B, than the channel D brings water to it) and then the fwell will ftop, and only the fmall channel CC will carry water to the fpring G, till the cavern B is filled to B again by the rill D; and then the water being at the top e of the channel E e F, that channel will act again as a fyphon, and carry off all the water from B to the foring G, and fo make a fwelling flow of water at G as before.

To illustrate this by a machine (Fig. 2.) let Abe a large wooden box, filled with water; and let a fmall pipe CC (the upper end of which is fixed into the bottom of the box) carry water from the box to G, where it will run off conflantly, like a fmall fpring. Let another fmall pipe D carry water from the fame box to the box or well B, from which let a fyphon E e Fproceed, and join with the pipe CC at f: the bore of the fyphon being larger than the bore of the feeding-pipe D. As the water from this pipe rifes in the well B, it will alfo rife as high in the fyphon E e F; and when the fyphon is E e 3 full

full to the top e, the water will run over the bend e, down the part e F, and go off at the mouth G; which will make a great fiream at G: and that fiream will continue, till the fyphon has carried off all the water from the well B; the fyphon carrying off the water fafter from Bthan the pipe D brings water to it : and then the fwell at G will ceafe, and only the water from the fmall pipe CC will run off at G, till the pipe D fills the well B again; and then the fyphon will run, and make a fwell at G as before.

And thus, we have an artificial reprefentation of an ebbing and flowing well, and of a reciprocating fpring, in a very natural and fimple manner.

HYDRAULICS. HYDRAULICS.

An Account of the Principles by which Mr. Blakey propofes to raife Water from Mines, or from Rivers, to fupply Towns and Gentlemen's Seats, by his new invented Fire-Engine, for which he has received His MAJESTY's Patent.

A LTHOUGH I am not at liberty to deicribe the whole of this fimple engine, yet I have the patentee's leave to defcribe fuch a one as will fhew the principles by which it acts.

In Fig. 4. of PLATE IV. let A be a large, ftrong, clofe vefiel; immerfed in water up to the cock b, and having a hole in the bottom, with a valve a upon it, opening upward within the veffel. A pipe BC rifes from the bottom of

22

of this veffel, and has a cock c in it near the top, which is fmall there, for playing a very high jet d. E is the little boiler (not fo big as a common tea-kettle) which is connected with the veffel A by the fteam pipe F_3 and G is a funnel, through which a little water must be occasionally poured into the boiler, to yield a proper quantity of steam. And a small quantity of water will do for that purpose, because steam posses as much space or bulk as the water does from which it proceeds.

The veffel A being immerfed in water up to the cock b, open that cock, and the water will rufh in, through the bottom of the veffel at a, and fill it as high up as the water flands on its outfide; and the water, coming into the veffel, will drive the air out of it (as high as the water rifes within it) through the cock b. When the water has done rufhing into the veffel, flut the cock b, and the valve a will fall down, and hinder the water from being pufhed out that way, by any force that preffeth on its furface. All the part of the veffel above b, will be full of common air, when the water rifes to b.

Shut the cock c, and open the cocks d and e; then pour as much water into the boiler E(through the funnel G) as will about half fill the boiler; and then flut the cock d, and leave the cock e open.

This done, make a fire under the boiler E, and the heat thereof will raife a fteam from the water in the boiler; and the fteam will make its way thence, through the pipe F, into the E e 4 veffel

veffel A; and the fleam will compress the air (above b) with a very great force upon the furface of the water in A.

When the top of the veffel A feels very hot by the fleam under it, open the cock c in the pipe C; and the air being flrongly comprefied in A, between the fleam and the water therein, will drive all the water out of the veffel A, up the pipe BC, from which it will fly up in a jet to a very great height.—In my fountain, which is made in this manner after Mr. Blakey's, three tea-cup fulls of water in the boiler will afford fleam enough to play a jet 30 feet high.

When all the water is out of the veffel A, and the comprefied air begins to follow the jet, open the cocks b and d to let the fleam out of the boiler E and veffel A, and flut the cock eto prevent any more fleam from getting into A; and the air will rufh into the veffel A through the cock b, and the water through the valve a; and fo the veffel will be filled up with water to the cock b as before. Then flut the cock band the cocks c and d, and open the cock e; and then, the next fleam that rifes in the boiler will make its way into the veffel A again; and the operation will go on, as above.

When all the water in the boiler E is evaporated, and gone off into fleam, pour a little more into the boiler, through the funnel G.

In order to make this engine raife water to any gentleman's house; if the house be on the bank of a river, the pipe BC may be continued up

24

25

up to the intended height, in the direction HI. Or, if the house be on the fide or top of a hill, at a diftance from the river, the pipe, through which the water is forced up, may be laid along on the hill, from the river or spring to the house.

The boiler may be fed by a finall pipe K, from the water that rifes in the main pipe BCHI; the pipe K being of a very fmall bore, fo as to fill the funnel G with water in the time that the boiler E will require a frefh fupply. And then, by turning the cock d, the water will fall from the funnel into the boiler. The funnel fhould hold as much water as will about half fill the boiler.

When either of these methods of raising water, perpendicularly or obliquely, is used, there will be no occasion for having the cock c in the main pipe BCHI: for such a cock is requisite only, when the engine is used as a fountain.

A contrivance may be very eafily made, from a lever to the cocks b, d, and e; fo that, by pulling the lever, the cocks b and d may be opened when the cock e muft be fhut; and the cock ebe opened when b and d muft be fhut.

The boiler E fhould be inclosed in a brick wall, at a little diffance from it, all around; to give liberty for the flames of the fire under the boiler to afcend round about it. By which means, (the wall not covering the funnel G) the force of the fteam will be prodigioufly increased by the heat round the boiler; and the funnel and water in it will be heated from the boiler; fo that, the boiler

boiler will not be chilled by letting cold water into it; and the rifing of the fleam will be fo much the quicker.

26

Mr. Blakey is the only perfon who ever thought of making ufe of air as an intermediate body between fteam and water: by which means, the fteam is always kept from touching the water, and confequently from being condenfed by it. And, on this new principle, he has obtained a patent: fo that no one (vary the engine how he will) can make ufe of air between fteam and water, without infringing on the patent, and being fubject to the penalties of the law.

This engine may be built for a trifling expence, in comparison of the common fire engine now in use: it will feldom need repairs, and will not confume half fo much fuel. And as it has no pumps with pistons, it is clear of all their friction: and the effect is equal to the whole strength or compressive force of the stream; which the effect of the common fire engine never is, on account of the great friction of the pistons in their pumps.

ARCHIMEDES's Screw-Engine for raifing Water.

In Fig. 1. of PLATE VI. ABCD is a wheel, which is turned round, according to the order of the letters, by the fall of water EF, which need not be more than three feet. The axle G of the wheel is elevated fo, as to make an angle of about 44 degrees with the horizon; and on the top of that axle is a wheel H, which turns fuch another wheel I of the fame number of

of teeth: the axle K of this laft wheel being parallel to the axle G of the two former wheels.

The axle G is cut into a double-threaded forew (as in Fig. 2.) exactly refembling the forew on the axis of the fly of a common jack, which muft be (what is called) a right-handed forew, like the wood-forews, if the firft wheel turns in the direction ABCD; but muft be a left-handed forew, if the ftream turns the wheel the contrary way. And, which-ever way the forew on the axle G be cut, the forew on the axle K muft be cut the contrary way; because these axles turn in contrary directions.

The fcrews being thus cut, they must be covered close over with boards, like those of a cylindrical cass, and then they will be spiral tubes. Or, they may be made of tubes of stiff leather, and wrapt round the axles in shallow grooves cut therein; as in Fig. 3.

The lower end of the axle G turns conftantly in the ftream that turns the wheel, and the lower ends of the fpiral tubes are open into the water. So that, as the wheel and axle are turned round, the water rifes in the fpiral tubes, and runs out at L, through the holes M, N, as they come about below the axle. These holes (of which there may be any number, as four or fix) are in a broad close ring on the top of the axle, into which ring, the water is delivered from the upper open ends of the fcrew-tubes, and falls into the open box N.

The lower end of the axle K turns on a gudgeon, in the water in N; and the fpiral tubes

tubes in that axle take up the water from N, and deliver it into fuch another box under the top of K; on which there may be fuch another wheel as I, to turn a third axle by fuch a wheel upon it.——And in this manner, water may be raifed to any given height, when there is a ftream fufficient for that purpofe to act on the broad float boards of the first wheel.

A quadruple Pump-Mill for raifing Water.

This engine is reprefented in PLATE VII. In which ABCD is a wheel, turned by water according to the order of the letters. On the horizontal axis are four fmall wheels, toothed almost half round: and the parts of their edges on which there are no teeth are cut down fo, as to be even with the bottoms of the teeth where they ftand.

The teeth of these four wheels take alternately into the teeth of four racks, which hang by two chains over the pullies \mathcal{Q} and L; and to the lower ends of these racks there are four iron rods fixed, which go down into the four forcing pumps, S, R, M and N. And, as the wheels turn, the racks and pump-rods are alternately moved up and down.

Thus, fuppole the wheel G has pulled down the rack I, and drawn up the rack K by the chain: as the laft tooth of G just leaves the uppermost tooth of I, the first tooth of H is ready to take into the lowermost tooth of the rack K and pull it down as far as the teeth go; and

and then the rack I is pulled upward through the whole fpace of its teeth, and the wheel G is ready to take hold of it, and pull it down again, and fo draw up the other. In the fame manner, the wheels E and F work the racks Oand P.

These four wheels are fixed on the axle of the great wheel in fuch a manner, with respect to the positions of their teeth; that, whilst they continue turning round, there is never one instant of time in which one or other of the pump-rods is not going down, and forcing the water. So that, in this engine, there is no occasion for having a general air-vessel to all the pumps, to procure a constant stream of water flowing from the upper end of the main pipe.

The piftons of these pumps are folid plungers, the same as described in the fifth Lecture of my book, to which this is a Supplement. See PLATE XI. Fig. 4. of that book, with the description of the figure.

From each of thefe pumps, near the loweft end, in the water, there goes off a pipe; with a valve on its fartheft end from the pump; and thefe ends of the pipes all enter one clofe box, into which they deliver the water: and into this box, the lower end of the main conduct pipe is fixed. So that, as the water is forced or pufhed into this box, it is also pufhed up the main pipe to the height that it is intended to be raifed.

There is an engine of this fort, defcribed in Ramelli's work : but I can truly fay, that I 2 never never faw it till fome time after I had made this model.

The faid model is not above twice as big as the figure of it, here defcribed. I turn it by a winch fixed on the gudgeon of the axle behind the water wheel; and, when it was newly made, and the piftons and valves in good order, I put tin pipes 15 feet high upon it, when they were joined together, to fee what it could do. And I found, that in turning it moderately by the winch, it would raife a hogfhead of water in an hour, to the height of 15 feet.

DIALLING.

The universal Dialling Cylinder.

N Fig. 1. of PLATE VIII. ABCD represented to the preference of th

There are 24 ftraight lines, drawn with a diamond, on the outfide of the glafs, equidiftant from each other, and all of them parallel to the axis. These are the hour-lines; and the hours are

DIALLING.

31

are fet to them as in the figure : the XII next B flands for midnight, and the opposite XII, next the board H, flands for mid-day or noon.

The axis being elevated to the latitude of the place, and the foot-board fet truly level, with the black line along its middle in the plane of the meridian, and the end N toward the north; the axis E F G will ferve as a ftile or gnomon, and caft a fhadow on the hour of the day, among the parallel hour lines when the fun fhines on the machine. For, as the fun's apparent diurnal motion is equable in the heavens, the fhadow of the axis will move equably in the tube; and will always fall upon that hour-line which is oppofite to the fun, at any given time.

The brafs plate AD, at the top, is parallel to the equator, and the axis EFG is perpendicular to it. If right lines be drawn from the center of this plate, to the upper ends of the equidiftant parallel lines on the outfide of the tube; thefe right lines will be the hour-lines on the equinoctial dial AD, at 15 degrees diftance from each other: and the hour-letters may be fet to them as in the figure. Then, as the fhadow of the axis within the tube comes on the hour-lines of the tube, it will cover the like hour-lines on the equinoctial plate AD.

If a thin horizontal plate ef be put within the tube, fo as its edge may touch the tube all around; and right lines be drawn from the center of that plate to those points of its edge which are cut by the parallel hour-lines on the tube; these right lines will be the hour-lines of a horizontal dial, for the latitude to which the tube is ele-6 vated. vated. For, as the fhadow of the axis comes fucceffively to the hour-lines of the tube, and covers them, it will then cover the like hourlines on the horizontal plate e f, to which the hours may be fet; as in the figure.

If a thin vertical plate gC, be put within the tube, fo as to front the meridian or 12 o'clock line thereof, and the edge of this plate touch the tube all around; and then, if right lines be drawn from the center of the plate to those points of its edge which are cut by the parallel hour-lines on the tube; these right lines will be the hour-lines of a vertical fouth-dial: and the shadow of the axis will cover them at the fame times when it covers those of the tube.

If a thin plate be put within the tube fo, as to decline, or incline, or recline, by any given number of degrees; and right lines be drawn from its center to the hour-lines of the tube; thefe right lines will be the hour-lines of a declining, inclining, or reclining dial, answering to the like number of degrees, for the latitude to which the tube is elevated.

And thus, by this fimple machine, all the principles of dialling are made very plain, and evident to the fight. And the axis of the tube (which is parallel to the axis of the world in every latitude to which it is elevated) is the ftile or gnomon for all the different kinds of fun-dials.

And laftly, if the axis of the tube be drawn out, with the plates AD, ef, and gC upon it; and fet it up in fun-fhine, in the fame polition as they were in the tube; you will have an equinoctial

DIALLING.

notical dial A D, a horizontal dial e f, and a vertical fouth dial g C; on all which, the time of the day will be fhewn by the fhadow of the axis or gnomon E F G.

Let us now suppose that, instead of a glass tube, ABCD is a cylinder of wood; on which the 24 parallel hour-lines are drawn all around, at equal diffances from each other; and that, from the points at top, where these lines end, right lines are drawn toward the center, on the flat furface AD: These right lines will be the hour-lines on an equinoctial dial, for the latitude of the place to which the cylinder is elevated above the horizontal foot or pedeftal H; and they are equidiftant from each other, as in Fig. 2. which is a full view of the flat furface or top AD of the cylinder, feen obliquely in Fig. 1. And the axis of the cylinder (which is a ftraight wire E F G all down its middle) is the flie or gnomon; which is perpendicular to the plane of the equinoctial dial, as the earth's axis is perpendicular to the plane of the equator.

To make a horizontal dial, by the cylinder, for any latitude to which its axis is elevated; draw out the axis and cut the cylinder quite through, as at $e \ b \ f \ g$, parallel to the horizontal board H, and take off the top part $e \ A \ D \ f \ e$; and the fection $e \ b \ f \ g \ e$ will be of an elliptical form, as in Fig. 3. Then, from the points of this fection (on the remaining part $e \ B \ C \ f$) where the parallel lines on the outfide of the cylinder meet it, draw right lines to the center of the fection; and they will be the true hour-lines for a horizontal dial, as $a \ b \ c \ d \ a$ in Fig. 3. which may be included in a circle drawn on that fection. F f

DIALLING.

Then put the wire into its place again, and it will be a flile for caffing a fladow on the time of the day, on that dial. So, E (Fig. 3.) is the flile of the horizontal dial, parallel to the axis of the cylinder.

To make a vertical fouth dial by the cylinder, draw out the axis, and cut the cylinder perpendicularly to the horizontal board H, as at giCkg, beginning at the hour line (Bg e A) of XII. and making the fection at right angles to the line SHN on the horizontal board. Then, take off the upper part g A D C, and the face of the fection thereon will be elliptical, as fhewn in Fig. 4. From the points in the edge of this fection, where the parallel hour-lines on the round furface of the cylinder meet it, draw right lines to the center of the fection; and they will be the true hour-lines on a vertical direct fouth dial, for the latitude to which the cylinder was elewated : and will appear as in Fig. 4. on which the vertical dial may be made of a circular shape, or of a fquare fhape as reprefented in the figure. And F will be its ftile parallel to the axis of the cylinder.

And thus, by cutting the cylinder any way, fo as its fection may either incline, or decline, or realine, by any given number of degrees; and from thole points in the edge of the fection where the outfide parallel hour-lines meet it, draw right lines to the center of the fection; and they will be the true hour lines, for the like declining, reclining, or inclining dial: And the axis of the sylinder will always be the gnomon or ftile of the dial. For, which-ever way the plane of the dial lies, its ftile (or the edge thereof that

34

J. Ferguson delin.

J.Mynde fo.

that calls the shadow on the hours of the day) must be parallel to the earth's axis, and point toward the elevated pole of the heavens.

To delineate a Sun-Dial on Paper; which, when pasted round a Cylinder of Wood, shall shew the Time of the Day, the Sun's Place in the Ecliptic; and his Altitude, at any Time of Observation. See PLATE IX.

Draw the right line a A B, parallel to the top of the paper; and, with any convenient opening of the compasses, set one foot in the end of the line at a, as a center, and with the other foot defcribe the quadrantal arc AE, and divide it into 90 equal parts or degrees. Draw the right line AC, at right angles to a AB, and touching the quadrant AE at the point A. Then, from the center a, draw right lines through as many degrees of the quadrant, as are equal to the fun's altitude at noon, on the longest day of the year, at the place for which the dial is to ferve; which altitude, at London, is 62 degrees : and continue thefe right lines till they meet the tangent line AC; and, from these points of meeting, draw straight lines across the paper, parallel to the first right line AB, and they will be the parallels of the fun's altitude, in whole degrees, from fun-rife till fun-fet, on all the days of the year. ---- Thefe parallels of altitude must be drawn out to the right line B D, which must be parallel to AC, and as far from it as is equal to the intended circumference of the cylinder on which the paper is to be pasted, when the dial is drawn upon it.

Divide the fpace between the right lines ACand BD (at top and bottom) into twelve equal Ff_2 parts

parts, for the twelve figns of the ecliptic; and, from mark to mark of thefe divisions at top and bottom, draw right lines parallel to AC and BD; and place the characters of the 12 figns in thefe twelve fpaces, at the bottom, as in the figure: beginning with & or Capricorn, and ending with \times or Pisces. The spaces including the figns should be divided by parallel lines into halves; and if the breadth will admit of it without confusion, into quarters also.

At the top of the dial, make a fcale of the months and days of the year, fo as the days may ftand over the fun's place for each of them in the figns of the ecliptic. The fun's place, for every day of the year, may be found by any common ephemeris: and here it will be beft to make use of an ephemeries for the second year after leap year; as the nearest mean for the fun's place on the days of the leap-year, and on those of the first, fecond, and third year after.

Compute the fun's altitude for every hour (in the latitude of your place) when he is in the beginning, middle, and end of each fign of the ecliptic; his altitude at the end of each fign being the fame as at the beginning of the next. And, in the upright parallel lines, at the beginning and middle of each fign, make marks for thefe computed altitudes among the norizontal parallels of altitude, reckoning them downward, according to the order of the numeral figures fet to them at the right hand, answering to the like divisions of the quadrant at the left. And, through these marks, draw the curve hour-lines, and let the hours to them, as in the figure, reckoning the forenoon hours downward, and the

the afternoon hours upward .---- The fun's altitude fhould also be computed for the half hours ; and the quarter lines may be drawn, very nearly in their proper places, by effimation and accuracy of the eye. Then, cut off the paper at the left hand, on which the quadrant was drawn, close by the right line AC, and all the paper at the right hand close by the right line BD; and cut it also close by the top and bottom horizontal lines; and it will be fit for pasting round the cylinder.

This cylinder is reprefented in miniature by Fig. I. PLATE X. It should be hollow, to hold the ftile DE when it is not used. The crooked end of the ftile is put into a hole in the top AD of the cylinder; and the top goes on tightifh, but must be made to turn round on the cylinder, like the lid of a paper fnuff-box. The ftile must stand straight out, perpendicular to the fide of the cylinder, just over the right line AB in PLATE IX, where the parallels of the fun's altitude begin : and the length of the ftile, or diftance of its point e from the cylinder, must be equal to the radius a A of the quadrant A E in PLATE IX.

The method of using this dial is as follows.

Flace the horizontal foot BC of the cylinder on a level table where the fun fhines, and turn the top A D till the ftile ftands just over the day of the then prefent month. Then turn the cylinder about on the table, till the fhadow of the ftile falls upon it, parallel to thefe upright lines which divide the figns; that is, till the fhadow be parallel to a fuppofed axis in the middle of the cylinder : and then, the point, or loweft end Ff 2 of

38

of the fhadow, will fall upon the time of the day, as it is before or after noon, among the curve hour-lines; and will fhew the fun's altitude at that time, amongst the crois parallels of his altitude, which go round the cylinder : and, at the fame time, it will fhew in what fign of the ecliptic the fun then is, and you may very nearly guess at the degree of the fign, by estimation of the eye.

The ninth plate, on which this dial is drawn, may be cut out of the book, and pafted round a cylinder whole length is 6 inches and 6 tenths of an inch below the moveable top; and its diameter 2 inches and 24 hundred parts of an inch—Or, I fuppofe the copper-plate prints of it may be had at Mr. Cadell's, bookfeller in the Strand, London. But it will only do for London, and other places of the fame latitude.

When a level table cannot be had, the dial may be hung by the ring F at the top. And when it is not ufed, the wire that ferves for a flile may be drawn out, and put up within the cylinder; and the machine carried in the pocket.

To make three Sun-dials upon three different Planes, fo as they may all shew the Time of the Day by one Gnomon.

On the flat board ABC, defcribe a horizontal dial, according to any of the rules laid down in the Lecture on Dialling; and to it fix its gnomon FGH, the edge of the fhadow from the fide FG being that which fhews the time of the day.

To this horizontal or flat board, join the upright board EDC, touching the edge GH of the gnomon. Then, making the top of the gnomon

gnomon at G the center of the vertical fouth dial, defcribe a fouth dial on the board E D C.

Laftly, on a circular plate I K defcribe an equinoctial dial, all the hours of which dial are equidiftant from each other; and making a flit c d in that dial, from its edge to its center, in the XII o'clock line; put the faid dial perpendicularly on the gnomon FG, as far as the flit will admit of; and the triple dial will be finished; the fame gnomon ferving all the three, and shewing the fame time of the day on each of them.

An universal Dial on a plain Cross.

This dial is reprefented by Fig. 1 of PLATE XI, and is moveable on a joint C, for elevating it to any given latitude, on the quadrant C $\circ 90$, as it ftands upon the horizontal board A. The arms of the crofs ftand at right angles to the middle part; and the top of it from a to n, is of equal length with either of the arms $n e \circ rm k$.

Having fet the middle line $t \ge t$ to the latitude of your place, on the quadrant, the board Alevel, and the point N northward by the needle; the plane of the crofs will be parallel to the plane of the equator; and the machine will be rectified.

Then, from III o'clock in the morning, till VI, the upper edge k l of the arm i o will caft a fhadow on the time of the day on the fide of the arm cm: from VI till IX the lower edge i of the arm i o will caft a fhadow on the hours on the fide o q. From IX in the morning to XII at noon, the edge a b of the top part a n will caft a fhadow on the hours on the arm n e f: from XII to III in the afternoon, the edge c d of the top F f 4 part part will caft a fhadow on the hours on the arm k l m: from III to VI in the evening, the edge g b will caft a fhadow on the hours on the part p s; and from VI till IX, the fhadow of the edge e f will fhew the time on the top part a n.

The breadth of each part, a b, e f, &c. muft be fo great as never to let the fhadow fall quite without the part or arm on which the heurs are marked, when the fun is at his greateft declination from the equator.

To determine the breadth of the fides of the arms which contain the hours, fo as to be in juft proportion to their length; make an angle ABC (Fig. 2.) of $23\frac{1}{2}$ degrees, which is equal to the fun's greateft declination: and fuppofe the length of each arm, from the fide of the long middle part, and also the length of the top part above the arms, to be equal to Bd.

Then, as the edges of the fbadow from each of the arms, will be parallelto Be, making an angle of $23\frac{1}{2}$ degrees with the fide Bd of the arm when the fun's declination is $23\frac{1}{2}$ degrees; 'tis plain, that if the length of the arm be Bd, the leaft breadth that it can have, to keep the edge Be of the fbadow Begd from going off the fide of the arm de before it comes to the end ed thereof, muft be equal to ed or dB. But in order to keep the fbadow within the quarter divisions of the hours, when it comes near the end of the arm, the breadth thereof fbould be ftill greater, fo as to be almost doubled, on account of the diffance between the tips of the arms.

To

To place the hours right on the arms, take the following method.

Lay down the crofs a c b d (Fig. 3.) on a fheet of paper; and with a black lead pencil, held clofe to it, draw its fhape and fize on the paper. Then taking the length a e in your compaffes, and fetting one foot in the corner a, with the other foot defcribe the quadrantal arc e f. Divide this arc into fix equal parts, and through the divifion marks draw right lines a g, a b, &cc.continuing three of them to the arm c e, which are all that can fall upon it; and they will meet the arm in these points through which the lines that divide the hours from each other (as in Fig. 1.) are to be drawn right acrofs it.

Divide each arm, for the three hours it contains, in the fame manner; and fet the hours to their proper places (on the fides of the arms) as they are marked in Fig. 3. Each of the hour fpaces fhould be divided into four equal parts, for the half hours and quarters, in the quadrant ef and right lines fhould be drawn through these division marks in the quadrant, to the arms of the cross in order to determine the places thereon where the fub-divisions of the hours must be marked.

This is a very fimple kind of univerfal dial; it is very eafily made, and will have a pretty uncommon appearance in a garden.——I have feen a dial of this fort, but never faw one of the kind that follows.

An

42

An univerfal Dial, shewing the Hours of the Day by a terrestrial Globe, and by the Shadows of several Gnomons, at the same Time: together with all the Places of the Earth which are then enlightened by the Sun; and those to which the Sun is then rifing, or on the Meridian, or Setting.

This dial (See PLATE XII.) is made of a thick fquare piece of wood, or hollow metal. The fides are cut into femicircular hollows, in which the hours are placed; the file of each hollow coming out from the bottom thereof, as far as the ends of the hollows project. The corners are cut out into angles, in the infides of which, the hours are alfo marked; and the edge of the end of each fide of the angle ferves as a ftile for caffing a fhadow on the hours marked on the other fide.

In the middle of the uppermoft fide or plane, there is an equinoctial dial; in the center whereof, an upright wire is fixt, for caffing a fhadow on the hours of that dial, and fupporting a fmall terreftrial globe on its top.

The whole dial ftands on a pillar, in the middle of a round horizontal board, in which there is a compass and magnetic needle, for placing the *meridian* ftile toward the fouth. The pillar has a joint with a quadrant upon it, divided into 90 degrees (fuppoled to be hid from fight under the dial in the figure) for fetting it to the latitude of any given place; the fame way as already defcribed in the dial on the cross.

The equator of the globe is divided into 24 equal parts, and the hours are laid down upon it

at these parts. The time of the day may be known by these hours, when the sun shines upon the globe.

To rectify and use this dial, fet it on a level table, or fole of a window, where the fun fhines, placing the meridian ftile due fouth, by means of the needle; which will be, when the needle points as far from the north fleur-de-lis toward the weft, as it declines weftward, at your place. Then bend the pillar in the joint, till the black line on the pillar comes to the latitude of your place in the quadrant.

The machine being thus rectified, the plane of its dial-part will be parallel to the equator, the wire or axis that fupports the globe will be parallel to the earth's axis, and the north pole of the globe will point toward the north pole of the heavens.

The fame hour will then be fhewn in feveral of the hollows, by the ends of the shadows of their refpective ftiles : The axis of the globe will caft a fhadow on the fame hour of the day, in the equinoctial dial, in the center of which it is placed, from the 20th of March to the 23d of September; and, if the meridian of your place on the globe be fet even with the meridian ftile, all the parts of the globe that the fun fhines upon, will answer to those places of the real earth which are then enlightened by the fun. The places where the lhade is just coming upon the globe, answer to all those places of the earth to which the fun is then fetting; as the places where it is going off, and the light coming on, answer to all the places of the earth where the fun is then rifing. And laftly, if the hour of VI be

be marked on the equator in the meridian of your place (as it is marked on the meridian of London in the figure) the division of the light and shade on the globe will shew the time of the day.

The northern file of the dial (oppofite to the fouthern or meridian one) is hid from fight in the figure, by the axis of the globe. The ours in the hollow to which that file belongs, are alfo fuppofed to be hid by the oblique view of the figure: but they are the fame as the hours in the front-hollow. Those alfo in the right and left hand femicircular hollows are mostly hid from fight; and fo alfo are all those on the fides next the eye of the four acute angles.

The construction of this dial is as follows, See PLATE XIII.

On a thick fquare piece of wood, or metal, draw the lines a c and b d, as far from each other as you intend for the thickness of the flile a b c dand in the fame manner, draw the like thickness of the other three fliles, e f g b, i k l m, and n o p q, all flanding outright as from the center.

With any convenient opening of the compaffes, as $a \ A$ (fo as to leave proper firength of ftuff when K I is equal to $a \ A$) fet one foot in a, as a center, and with the other foot defcribe the quadrantal arc $A \ c$. Then without altering the compaffes, fet one foot in b as a center, and with the other foot defcribe the quadrant $d \ B$. All the other quadrants in the figure muft be defcribed in the fame manner, and with the

the fame opening of the compafies, on their centers e, f; i, k; and n, o: and each quadrant divided into 6 equal parts, for fo many hours, as in the figure; each of which parts must be fub-divided into 4, for the half hours and quarters.

At equal diffances from each corner, draw the right lines Ip, and Kp, Lq, and Mq, Nr, and Or, Ps, and $\mathcal{Q}s$; to form the four angular hollows lpK, LqM, NrO, and $Ps\mathcal{Q}$; making the diffances between the tips of thefe hollows, as IK, LM, NO, and $P\mathcal{Q}$, each equal to the radius of the quadrants; and leaving fufficient room within the angular points, p, q, r, and s, for the equinoctial circle in the middle.

To divide the infides of these angles properly for the hour-spaces thereon, take the following method.

Set one foot of the compaffes in the point I. as a center; and open the other to K, and with that opening, defcribe the arc Kt: then, without altering the compasses, set one foot in K. and with the other foot defcribe the arc It. Divide each of these arcs, from I and K to their interfection at t, into four equal parts; and from their centers I and K, through the points of division, draw the right lines I 3, I 4, I 5, 16, 17; and K2, K1, K12, K11; and they will meet the fides Kp and Ip of the angle Ip Kwhere the hours thereon must be placed. And thefe hour-fpaces in the arcs must be fubdivided into four equal parts, for the half hours and quarters .---- Do the like for the other three angles, and draw the dotted lines, and fet the hours

46

hours in the infides where those lines meet them. as in the figure : and the like hour-lines will be parallel to each other in all the quadrants and in all the angles.

Mark points for all these hours, on the upper fide and cut out all the angular hollows, and the quadrantal ones quite through the places where their four gnomons must stand ; and lay down the hours on their infides, as in PLATE XII, and then fet in their four gnomons, which must be as broad as the dial is thick; and this breadth and thickness must be large enough to keep the shadows of the gnomons from ever falling quite out at the fides of the hollows, even when the fun's declination is at the greatest.

Laftly, draw the equinoctial dial in the middle, all the hours of which are equidiftant from each other; and the dial will be finished.

As the fun goes round, the broad end of the shadow of the stile a b c d will shew the hours in the quadrant A c, from fun rife till VI in the morning; the fhadow from the end M will fhew the hours on the fide Lq from V to IX in the morning; the shadow of the stile efg b in the quadrant D g (in the long days) will fhew the hours from fun-rife till VI in the morning ; and the shadow of the end N will shew the morning hours, on the fide Or, from III to VII.

Just as the shadow of the northern stile a b c d goes off the quadrant Ac, the fhadow of the fouthern stile i k 1 m begins to fall within the quadrant Fl, at VI in the morning; and thews the time, in that quadrant, from VI till XII at noon ; 4

noon; and from noon till VI in the evening in the quadrant m E. And the fhadow of the end O fhews the time from XI in the forenoon till III in the afternoon, on the fide r N; as the fhadow of the end P fhews the time from IX in the morning till I o'clock in the afternoon, on the fide \mathcal{Q} s.

At noon, when the fladow of the eaftern file efgb goes off the quadrant bC (in which it fhewed the time from VI in the morning till noon, as it did in the quadrant gD from funrife till VI in the morning) the fladow of the weftern ftile $n \circ pq$ begins to enter the quadrant Hp; and flows the hours thereon from XII at noon till VI in the evening; and after *ibat* till fun-fet, in the quadrant qG: and the end Qcafts a fladow on the fide Ps from V in the evening till IX at night, if the fun be not fet before that time.

The fhadow of the end I fhews the time on the fide K p from III till VII in the afternoon; and the fhadow of the ftile a b c d fhews the time from VI in the evening till the fun fets.

The fhadow of the upright central wire, that fupports the globe at top, fhews the time of the day, in the middle or equinoctial dial, all the fummer half year, when the fun is on the north fide of the equator.

In this fupplement to my book of Lectures, all the machines that I have added to my apparatus, fince that book was printed, are defcribed, excepting two; one of which is a model of

48

of a mill for fawing timber, and the other is a model of the great engine at London-bridge, for raifing water. And my reafons for leaving them out are as follow.

First, I found it impossible to make such a drawing of the faw-mill as could be understood; because, in whatever view it be taken, a great many parts of it hid others from sight. And, in order to shew it in my Lectures, I am obliged to turn it into all manner of positions.

Secondly, Becaufe any perfon who looks on Fig. 1. of P_{LATE} XII in the book, and reads the account of it in the fifth Lecture therein, will be able to form a very good idea of the London-bridge engine, which has only two wheels and two trundles more than there are in Mr. Alderfea's engine, from which the faid figure was taken.
